Demonstration. Let EDAFG, (*ibid.* fig. 3.) represent the eighth part of a sphere, where the quadrantal planes EDFG, EDBC, are both perpendicular to the quadrantal plane ADFB; and the quadrantal plane ADGC is perpendicular to the plane EDFG; and the spherical triangle ABC is right-angled at B, where CA is the hypotenuse, and BA, BC, are the legs.

To the arches GF, CB, draw the tangents HF, OB, and the sines GM, CI, on the radii DF, DB; also draw BL the sine of the arch AB, and CK the sine of AC; and then join IK and OL. Now HF, OB, GM, CI, are all perpendicular to the plane ADFB. And HD, GK, OL, lie all in the same plane ADGC. Also FD, IK, BL, lie all in the same plane ADGC. Therefore, the right-angled triangles HFD, CIK, ODL, having the equal angles HDF, CKI, OLB, are similar. And CK : DG :: CI : GM; that is, as the sine of the hypotenuse : rad. :: sine of a leg : sine of its opposite angle. For GM is the sine of the arc GF, which measures the angle CAB. Also, LB : DF :: BO : FH; that is, as the sine of a leg : radius :: tangent of the other leg : tangent of its opposite angle. Q. E. D.

Hence it follows, that the sines of the angles of any oblique spherical triangle ACD (*ibid.* n° 2.) are to one another, directly, as the sines of the opposite sides. Hence it also follows, that, in right-angled spherical triangles, having the same perpendicular, the sines of the bases will be to each other, inversely, as the tangents of the angles at the bases.

THEOREM II. In any right-angled spherical triangle ABC (*ibid.* n° 3.) it will be, As radius is to the co-sine of one leg, so is the co-sine of the other leg to the co-sine of the hypotenuse.

Hence, if two right-angled spherical triangles ABC, CBD (*ibid.* n° 2.) have the same perpendicular BC, the co-sines of their hypotenuses will be to each other, directly, as the co-sines of their bases.

Spherical. THEOREM III. In any spherical triangle it will be, As radius is to the sine of either angle, so is the co-sine of the adjacent leg to the co-sine of the opposite angle.

Hence, in right-angled spherical triangles, having the same perpendicular, the co-sines of the angles at the base will be to each other, directly, as the sines of the vertical angles.

THEOREM IV. In any right-angled spherical triangle it will be, As radius is to the co-sine of the hypotenuse, so is the tangent of either angle to the co-tangent of the other angle.

As the sum of the sines of two unequal arches is to their difference, so is the tangent of half the sum of those arches to the tangent of half their difference: and as the sum of the co-sines is to their difference, so is the co-tangent of half the sum of the arches to the tangent of half the difference of the same arches.

THEOREM V. In any spherical triangle ABC (*ibid.* n° 4. and 5.) it will be, As the co-tangent of half the sum of half their difference, so is the co-tangent of

half the base to the tangent of the distance (DE) of the perpendicular from the middle of the base.

Since the last proportion, by permutation, becomes

$$\frac{AC+BC}{2} \text{ co-tang. } AE :: \text{tang. } \frac{AC-BC}{2}$$

tang. DE, and as the tangents of any two arches are, inversely, as their co tangents; it follows, therefore, that $\text{tang. } AE :: \text{tang. } \frac{AC+BC}{2} :: \text{tang. } \frac{AC-BC}{2}$:

tang. DE; or, that the tangent of half the base is to the tangent of half the sum of the sides, as the tangent of half the difference of the sides to the tangent of the distance of the perpendicular from the middle of the base.

THEOREM VI. In any spherical triangle ABC (*ibid.* n° 4.) it will be, As the co-tangent of half the sum of the angles at the base is to the tangent of half their difference, so is the tangent of half the vertical angle to the tangent of the angle which the perpendicular CD makes with the line CF bisecting the vertical angle.

The Solution of the Cases of right-angled spherical Triangles, (*ibid.* n° 3.)

| Case | Given | Sought | Solution |
|------|-------------------------------------|----------------------|-----------------------------------------------------------------------------------|
| 1 | The hyp. AC and one angle A | The opposite leg BC | As radius : sine hyp. AC :: sine A : sine BC (by the former part of theor. 1.) |
| 2 | The hyp. AC and one angle A | The adjacent leg AB | As radius : co-sine of A :: tang. AC : tang. AB (by the latter part of theor. 1.) |
| 3 | The hyp. AC and one angle A | The other angle C | As radius : co-sine of AC :: tang. A : co-tang. C (by theorem 4.) |
| 4 | The hyp. AC and one leg AB | The other leg BC | As co-sine AB : radius :: co-sine AC : co-sine BC (by theorem 2.) |
| 5 | The hyp. AC and one leg AB | The opposite angle C | As sine AC : radius :: sine AB : sine C (by the former part of theorem 1.) |
| 6 | The hyp. AC and one leg AB | The adjacent angle A | As tang. AC : tang. AB :: radius : co-sine A (by theorem 1.) |
| 7 | One leg AB and the adjacent angle A | The other leg BC | As radius : sine AB :: tangent A : tangent BC (by theorem 4.) |
| 8 | One leg AB and the adjacent angle A | The opposite angle C | As radius : sine A :: co-sine of AB : co-sine of C (by theorem 3.) |
| 9 | One leg AB and the adjacent angle A | The hyp. AC | As co-sine of A : radius :: tang. AB : tang. AC (by theorem 1.) |
| 10 | One leg BC and the opposite angle A | The other leg AB | As tang. A : tang. BC :: radius : sine AB (by theorem 4.) |
| 11 | One leg BC and the opposite angle A | The adjacent angle C | As co-sine BC : radius :: co-sine of A : sine C (by theorem 3.) |
| 12 | One leg BC and the opposite angle A | The hyp. AC | As sine A : sine BC :: radius : sine AC (by theorem 1.) |
| 13 | Both legs AB and BC | The hyp. AC | As radius : co-sine AB :: co-sine BC : co-sine AC (by theorem 2.) |
| 14 | Both legs AB and BC | An angle, suppose A | As sine AB : radius :: tang. BC : tang. A (by theorem 4.) |
| 15 | Both angles A and C | A leg, suppose AB | As sine A : co-sine C :: radius : co-sine AB (by theorem 3.) |
| 16 | Both angles A and C | The hyp. AC | As tang. A : co-tang. C :: radius : co-sine AC (by theorem 4.) |

Note, The 10th, 11th, and 12th cases are ambiguous; since it cannot be determined by the data, whether A, B, C, and AC, be greater or less than 90 degrees each.

The Solution of the CASES of oblique spherical Triangles, (*ibid.* n° 4. and 5.)

| Case | Given | Sought | Solution |
|------|----------------------------------------------------------|---------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1 | Two sides AC, BC, and an angle A opposite to one of them | The angle B opposite to the other | As sine BC : sine A :: sine AC : sine B (by theorem 1.) Note, this case is ambiguous when BC is less than AC; since it cannot be determined from the data whether B be acute or obtuse. |
| 2 | Two sides AC, BC, and an angle A opposite to one of them | The included angle ACB | Upon AB produced (if need be) let fall the perpendicular CD : then (by theorem 4.) rad. : co-sine AC :: tang. A : co-tang. ACD; but (by theorem 1.) as tang. BC : tang. AC :: co-sine ACD : co-sine BCD. Whence ACB = ACD ± BCD is known. |
| 3 | Two sides AC, BC, and an angle opposite to one of them | The other side AB | As rad. : co-sine A :: tang. AC : tang. AD (by theor. 1.) and (by theor. 2.) as co-sine AC : co-sine BC :: co-sine AD : co-sine BD. Note, this and the last case are both ambiguous when the first is so. |
| 4 | Two sides AC, AB, and the included angle A | The other side BC | As rad. : co-sine A :: tang. AC : tang. AB (by theor. 1.) whence AD is also known : then (by theor. 2.) as co-sine AD : co-sine BD :: co-sine AC : co-sine BC. |
| 5 | Two sides AC, AB, and the included angle A | Either of the other angles, suppose B | As rad. : co-sine A :: tang. AC : tang. AD (by theor. 1.) whence BD is known : then (by theor. 4.) is sine BD : sine AD :: tang. A : tang. B. |
| 6 | Two angles A, ACB, and the side AC betwixt them | The other angle B | As rad. : co-sine AB :: tang. A : co-tang. ACD (by theorem 4.) whence BCD is also known : then (by theor. 3.) as sine ACD : sine BCD :: co-sine A : co-sine B. |
| 7 | Two angles A, ACB, and the side AC betwixt them | Either of the other sides, suppose BC | As rad. : co-sine AC : tang. A : co-tang. ACD (by theorem 4.) whence BCD is also known : then, as co-sine BCD : co-sine ACD :: tang. AC : tang. BC (by theor. 1.) |
| 8 | Two angles A, B, and a side AC opposite to one of them | The side BC opposite the other | As sine B : sine AC :: sine A : sine BC (by theorem 1.) |
| 9 | Two angles A, B, and a side AC opposite to one of them | The side AB betwixt them | As rad. : co-sine A :: tang. AC : tang. AD (by theor. 1.) and as tang. B : tang. A :: sine AD : sine BD (by theorem 4.) whence AB is also known. |
| 10 | Two angles A, B, and a side AC opposite to one of them | The other angle ACB | As rad. : co-sine AC :: tang. A : co-tang. ACD (by theorem 4.) and as co-sine A : co-sine B :: sine ACD : sine BCD (by theor. 3.) whence ACB is also known. |
| 11 | All the three sides AB, AC, and BC | An angle, suppose A | As tang. $\frac{AC+BC}{2}$:: tang. $\frac{AC-BC}{2}$: tang. DE, the distance of the perpendicular from the middle of the base (by theorem 6.) whence AD is known : then, as tang. AC : tang. A : AD :: rad. : co-sine A (by theor. 1.) |
| 12 | All the three angles A, B, and ACB | A side, suppose AC | As co-tang. $\frac{ABC+A}{2}$: tang. $\frac{ABC-A}{2}$:: tang. $\frac{ACB}{2}$: tan. of the angle included by the perpendicular and a line bisecting the vertical angles : whence ACD is also known : then (by theorem 5.) tang. A : co-tang. ACD :: rad. : co-sine AC. |

T R I

TRIHLATÆ, *tres* "three," and *hilum* "an external mark on the seed;" the name of the 23d class in Linnæus's Fragments of a Natural Method; consisting of plants with three seeds, which are marked with an external cicatrix or scar, where they are fastened within the fruit. See BOTANY, p. 1237.

TRIM, implies in general the state or disposition by which a ship is best calculated for the several purposes of navigation.

T R I

Thus the trim of the hold denotes the most convenient and proper arrangement of the various materials contained therein relatively to the ship's motion or stability at sea. The trim of the masts and sails is also their most apposite situation with regard to the construction of the ship and the effort of the wind upon her sails.

As the stowage of the hold, or the disposition of the several articles of the cargo, considerably affects the

Fig. 1. Rectangular TRIGONOMETRY

Plate CCLXXXVII

Fig. 2. Oblique angled TRIGONOMETRY

Fig. 3. Spherical TRIGONOMETRY

A. Bell, sculp.

the ship's motion and stability, it will be necessary to give a general idea of the action of a heavy body upon the fluid that supports it, and the re-action of the fluid on the floating body.

The whole weight of any body, then, may be considered as united in its centre of gravity; so that, if it were suspended by a line fastened to this centre, the line would hang in a perpendicular position, as directed through the centre of gravity to the centre of the earth. A body which floats in a fluid is not, however, supported by its centre of gravity, but by the compression of the surrounding filaments of water: and each of these, being considered as infinitely small, will act upon a very minute portion of the surface of the floating body with regard to the specific gravity, and conform to a principle applicable to all fluids, in proportion to the height of these filaments, viz. that the weight of a column of any fluid will be in proportion to the specific gravity of the fluid and the height of the column multiplied by its base.

But as heavy bodies endeavour, by their gravity, to approach the centre of the earth in a vertical line passing through their centres; so the pressure of fluids endeavours to carry bodies in a vertical, tending from the centre of the earth towards their surface, and passing through the centre of gravity of the submerged part, which forces them towards the surface. So, in any submerged body at rest, these two opposite forces coincide in the same vertical, acting in a direction quite contrary to each other.

From this theory it results, that the stability or trim of a ship chiefly depends upon her construction, as considering the bottom to be homogeneous. This, however, can only happen when her cargo consists of the same materials throughout, as with corn, salt, or any species stowed in bulk, and when her hold is entirely filled. For if the ship has not sufficient breadth to resist the effort of the wind upon her sails; or if she is built too high or too sharp in the floor, her centre of gravity will be too high, and she will be very crank, i. e. apt to overturn.

But as the stiffness of a ship, or quality to carry sail without danger of overturning, depends very much on the stowage of the hold, the centre of gravity may thereby be considerably lowered, by which her stability will be increased in proportion. It is a general maxim amongst mariners, that a ship will not carry sufficient sail till she is laden so deep that the surface of the water may glance on her extreme breadth amidships. She must therefore have a great deal of weight, as ballast, &c. to bring her to this situation, which is called a *good sailing trim*.

Several circumstances are also to be particularly considered with regard to the quality, weight, and stowage of the ballast. The centre of gravity being placed too high, will render the ship incapable of carrying a sufficient quantity of sail: and by having it too low, she will be in danger of rolling away her masts. When it is placed too far forward, the ship will pitch, and labour heavily; and when too far aft, she will occasionally be exposed to the circumstance of a pooping sea. These extremes being carefully avoided, it remains to proportion the contents of every part of the hold to its capacity, and to place the lightest materials uppermost.

VOL. X.

TRIM, when applied to the sails, denotes the general arrangement which is best calculated to accelerate the ship's course, according to the direction of the wind.

If the ship were always to sail before the wind, it would be a very simple operation to trim the sails; because nothing else could be required than to dispose them so as to receive the greatest possible effort of the wind, which is evidently performed by arranging them at right angles with its direction. But when the current of wind acts more directly upon the ship's side, it necessarily falls more obliquely on the surface of the sails, so as to diminish their effort to push the ship forward, and to augment their tendency to make her incline to one side. Hence we may conclude, that an increase of the wind, when accompanied with a variation unfavourable to the ship's course, will by no means augment her velocity; because the force previously employed to push her forward, will afterwards operate to overturn her; and because this impression renders it necessary to reduce the quantity of sail; the effort of which is farther diminished by the obliquity of the action of the wind upon its surface.

By this theory it appears, that the effect of the wind to advance the ship decreases in proportion to its obliquity with any sail upon which it operates. The mechanical disposition of the sails, according to every direction of the wind upon their surfaces, is copiously described in the article *CLOSE-HAULED, SAILING, and TACKLING*.

Trim, when expressed of the masts, denotes their position with regard to the ship and to each other. Thus, in the latter sense, they should neither be too near nor too far apart, and in the former they should not be too far forward or aft; and, according to the situation or quality which communicates a greater velocity to the vessel, they should either be upright, or inclining aft or forward.

TRINGA, the SANDPIPER, in ornithology, a genus of birds, belonging to the order of gallæ. The beak is somewhat cylindrical, and as long as the head; the nostrils are linear; and there are four toes on the feet, the hind one consisting of one joint, and elevated above the ground. There are 23 species; of which the most remarkable are,

1. The vanellus, or lapwing, inhabits most of the heaths and marshy grounds of this island. Their length is about $13\frac{1}{2}$ inches, the breadth $2\frac{1}{2}$ feet. The bill is black: the crown of the head of a shining blackness: the crest of the same colour, consisting of about 20 slender unwebbed feathers of unequal lengths: the longest are 4 inches: the cheeks and sides of the neck are white, but beneath each eye is a black line: the throat and fore-part of the neck are black: the plumage on the hind-part is mixed with white, ash-colour, and red: the back and scapulars are of a most elegant glossy green; and the latter finely varied with purple: the lesser covert feathers of the wings are of a resplendent black blue and green: the greater quill-feathers black, but the ends of the four first are marked with a white spot: the upper half of the lesser quill feathers are black: the lower white: the breast and belly are white: the vent-feathers and covers of the tail orange-colour: the tail consists of 12 feathers; the outmost on each

Tringa. side is white, marked on the upper end of the inner web with a dusky spot; the upper half of all the others are black, tipped with a dirty white; their lower half of a pure white; the legs are red; the irides hazel. The female is less than the male. Merret, in his Pinax, p. 182, says, that there is in Cornwall a bird related to this; but less than a thrush, having blue feathers and a long crest.—The lapwing lays four eggs, making a slight nest with a few bents. The eggs have an olive cast, and are spotted with black. The young, as soon as hatched, run like chickens: the parents show remarkable solicitude for them, flying with great anxiety and clamour near them, striking at either men or dogs that approach, and often flutter along the ground like a wounded bird, to a considerable distance from their nest, to delude their pursuers; and to aid the deceit, become more clamorous when most remote from it: the eggs are held in great esteem for their delicacy, and are sold by the London poulterers for three shillings the dozen. In winter, lapwings join in vast flocks; but at that season are very wild: their flesh is very good, their food being insects and worms. During October and November, they are taken in the fens in nets, in the same manner that ruffs are; but are not preserved for fattening, being killed as soon as caught.

2. The *Squatarola*, or grey sandpiper, is in length 12 inches; in breadth 24: the bill black, about an inch long, strong and thick: the head, back, and coverts of the wings are black, edged with greenish ash-colour and some white; cheeks and throat white, marked with oblong dusky spots: the belly and thighs white; the exterior webs of the quill-feathers black, the lower part of the interior webs of the four first white; the rump white: the tail marked with transverse bars of black and white: the legs of a dirty green: the back toe very small. These appear in small flocks in the winter-time, but are not very common: their flesh is very delicate.

3. The *pugnax*. The males of this species, called *ruffs*, assume such variety of colours in several parts of their plumage, that it is scarce possible to see two alike; but the great length of the feathers on the neck, that gives name to them, at once distinguish these from all other birds. On the back of their necks is a singular tuft of feathers spreading wide on both sides. These, and the former, in some are black; in others white, yellow, or ferruginous; but this tuft and the ruffs frequently differ in colours in the same bird. The feathers that bear an uniformity of colouring through each individual of this sex are the coverts of the wings, which are brown inclining to ash colour; the feathers on the breast, which are often black or dusky; the four exterior feathers of the tail, which are of a cinereous brown; and the four middle, which are barred with black and brown: the bill is black towards the end, red at the base. The legs in all are yellow. In moulting they lose the character of the long neck-feathers, nor do they recover it till after their return to the fens the spring following. It is then they regain that ornament, and at the same time a set of small pear-shaped yellow pimples break out in great numbers on their face above the bill.—The stags, or male birds of the first year, want these marks, and have sometimes been mistaken for a new species of tringa; but they may be easily known by the colours of the

coverts of the wings, and the middle feathers of the tail.—The older the birds are, the more numerous the pimples, and the fuller and longer the ruffs.

The length of the male to the tip of the tail is one foot, the breadth two; of the reeve or female, ten inches, the breadth nineteen; the weight of the former when just taken is seven ounces and a half; of the latter only four. The reeves never change their colours, which are pale brown; the back spotted with black, slightly edged with white; the tail brown, the middle feathers spotted with black; the breast and belly white; the legs of a pale dull yellow.

These birds appear in the fens in the earliest spring, and disappear about Michaelmas. The reeves lay four eggs in a tuft of grass, the first week in May, and sit about a month. The eggs are white, marked with large rusty spots. Fowlers avoid in general the taking of the females; not only because they are smaller than the males, but that they may be left to breed.

Soon after their arrival, the males begin to hill, that is, to collect on some dry bank near a splash of water, in expectation of the females, who resort to them. Each male keeps possession of a small piece of ground, which it runs round till the grass is worn quite away, and nothing but a naked circle is left. When a female lights, the ruffs immediately fall to fighting. It is a vulgar error, that ruffs must be fed in dark lest they should destroy each other by fighting on admission of light. The truth is, every bird takes its stand in the room as it would in the open fen. If another invades its circle, an attack is made, and a battle ensues. They make use of the same action in fighting as a cock, place their bills to the ground and spread their ruffs. Mr Pennant says, he has set a whole room-full a-fighting, by making them move their stations; and after quitting the place, by peeping through a crevice, seen them resume their circles and grow pacific.

When a fowler discovers one of those hills, he places his net over night, which is of the same kind as those that are called *clap* or *day nets*; only it is generally single, and is about fourteen yards long and four broad. The fowler resorts to his stand at day-break, at the distance of one, two, three, or four hundred yards from the nets, according to the time of the season; for the later it is, the fiercer the birds grow. He then makes his first pull, taking such birds as he finds within reach: after that he places his stub birds or stakes to entice those that are continually traversing the fen. An old fowler told our author that he once caught forty-four birds at the first haul, and in all six dozen that morning. When the stakes are set, seldom more than two or three are taken at a time. A fowler will take forty or fifty dozens in a season.—These birds are found in Lincolnshire, the isle of Ely, and in the East Riding of York. They visit a place called *Martin Mere* in Lancashire, the latter end of March or beginning of April; but do not continue there above three weeks; where they are taken in nets, and fattened for the table with bread and milk, hempseed, and sometimes boiled wheat; but if expedition is required, sugar is added, which will make them in a fortnight's time a lump of fat: they then sell for two shillings or half a crown a piece. Judgment is required in taking the proper time for killing.

Tringa.

killing them, when they are at the highest pitch of fatness; for if that is neglected, the birds are apt to fall away. The method of killing them is by cutting off their head with a pair of scissars: the quantity of blood that issues is very great, considering the size of the bird. They are dressed like the woodcock, with their innards; and, when killed at the critical time, say the Epicures, are the most delicious of all morrels.

4. The canutus, or knot, has the forehead, chin, and lower part of the neck, brown, inclining to ash-colour; the back and scapulars deep brown, edged with ash-colour; the coverts of the wings with white, the edges of the lower order deeply so, forming a white bar; the breast, sides, and belly white, the two first streaked with brown; the coverts of the tail marked with white and dusky spots alternately; the tail ash-coloured, the outermost feather on each side white; the legs of a bluish grey; and the toes, as a special mark, divided to the very bottom; the weight four ounces and a half.—These birds, when fattened, are preferred by some to the ruffs themselves. They are taken in great numbers on the coasts of Lincolnshire, in nets such as employed in taking ruffs; with two or three dozens of stales of wood painted like the birds, placed within; fourteen dozens have been taken at once. Their season is from the beginning of August to that of November. They disappear with the first frosts. Camden says they derive their name from king Canute, Knute, or Knout, as he is sometimes called; probably because they were a favourite dish with that monarch. We know that he kept the feast of the purification of the Virgin Mary with great pomp and magnificence at Ely; and this being one of the fen-birds, it is not unlikely but he met with it there.

5. The morinellus, turnstone, or sea-dottrel, is about the size of a thrush; the forehead and throat are ash-coloured; the head, whole neck and coverts of the wings, are of a deep brown, edged with a pale reddish brown; the scapular feathers are of the same colour, very long, and cover the back; that and the rump are white, the last marked with a large triangular black spot; the tail consists of twelve feathers, their lower half is white, the upper black, and the tips white: the quill feathers are dusky, but from the third or fourth the bottoms are white; the legs are short, and of an orange colour.—These birds take their name from their method of searching for food, by turning up small stones with their strong bills to get at the insects that lurk under them.

6. The ochropus, or green sandpiper. This beautiful species is not very common in these kingdoms. The head and hind part of the neck are of a brownish ash-colour, streaked with white; the under part mottled with brown and white; the back, scapular, and coverts of the wings are of a dusky green, glossy and resplendent as silk, and elegantly marked with small white spots; the lesser quill-feathers of the same colours; the under sides of the wings are black, marked with numerous white lines pointing obliquely from edges of the feather to the shaft, representing the letter V; the rump is white; the tail of the same colour.—Except in pairing time, it is a solitary bird: it is never found near the sea; but frequents rivers, lakes, and other fresh waters. In France it is highly esteem-

ed for its delicate taste; and is taken with limed twigs placed near its haunts.

7. The hypoleucos, or common sandpiper, agrees with the former in its manners and haunts; but is more common: its note is louder and more piping than others of this genus. Its head is brown, streaked with downward black lines; the neck an obscure ash-colour; the back and coverts of the wings brown, mixed with a glossy green, elegantly marked with transverse dusky lines; the breast and belly are of a pure white; the quill-feathers and the middle feathers of the tail are brown; the legs of a dull pale green.

8. The alpina, or dunling sandpiper, is at once distinguished from the others by the singularity of its colours. The back, head, and upper part of the neck are ferruginous, marked with large black spots; the lower part of the neck white, marked with short dusky streaks; the coverts of the wings ash-colour; the belly white, marked with large black spots, or with a black crescent pointing towards the thighs; the tail is ash-coloured; legs black; toes divided to their origin. In size it is superior to that of a lark. These birds are found on our sea-coasts; but may be reckoned among the more rare kinds. They lay four eggs of a dirty white colour, blotched with brown round the thicker end, and marked with a few small spots of the same colour on the smaller end. They are common on the Yorkshire coasts, and esteemed a great delicacy.

9. The cinclus, or purr, is in length $7\frac{1}{2}$ inches; extent 14; the head and hind part of the neck are ash-coloured, marked with dusky lines; a white stroke divides the bill and eyes; the back is of a brownish ash-colour; the breast and belly white; the coverts of the wings and tail a dark brown, edged with light ash-colour or white; the upper part of the quill-feathers dusky, the lower white; the legs of a dusky green; the toes divided to their origin. The bill an inch and a half long, slender and black; irides dusky.—These birds come in prodigious flocks on our sea-coasts during the winter: in their flight they perform their evolutions with great regularity; appearing like a white or a dusky cloud, as they turn their backs or their breasts towards you. They leave our shores in spring, and retire to some unknown place to breed. They were formerly a well known dish at our tables, under the name of *flints*.

TRINIDAD, or TRINITY-ISLAND, is situated in the Atlantic or American ocean, between 60° and 62° of west longitude, and between 9° and 11° of north latitude; it is about 90 miles long, and 60 broad. The soil is fruitful, producing sugar, cotton, fine tobacco, Indian, corn and fruits; but the air is unhealthy.

TRINIDAD, a port-town of Mexico, in America, situated in the province of Guatimala, 120 miles south-east of the city of Guatimala. W. Long. 94° N. Lat. 13° . It is an open town; but very important, because there is no other harbour on this coast.

TRINITARIANS, those who believe in the Trinity; those who do not believe therein being called *Antitrinitarians*.

TRINITARIANS, also denote an order of religious instituted at Rome in the year 1198, under the pontificate of Innocent III. the founders whereof were John de Matha and Felix de Valois. His holiness gave them

Trinidad,
Trinitarians

Trinity
||
Tripod.

permission to establish this order for the deliverance of captives, who groaned under the tyranny of the infidels: he gave them as a habit a white gown ornamented with a red and blue cross. After the death of the two founders, pope Honorius III. continued the order; and their rule was approved by his successor Clement IV. in 1367. At first they were not permitted to eat flesh; and when they travelled, were to ride only upon asses. But their rule was corrected and mitigated by the bishop of Paris, and the abbots of St Victor and St Genevieve, who allowed them to eat any kind of food, and to use horses. This order possesses about 250 convents in 13 different provinces: six of which are in France; namely, France, Normandy, Picardy, Champagne, Languedoc, and Provence; three in Spain, viz. New Castile, Old Castile, and Arragon; one is in Italy, and one in Portugal. There was formerly the province of England, where this order had 43 houses; that of Scotland, where it had nine; and that of Ireland, where it had 52; besides a great number of monasteries in Saxony, Hungary, Bohemia, and other countries. The convent of Cerroty in France is head of the order.

TRINITY, in theology, the ineffable mystery of three persons in one God; Father, Son, and Holy Spirit.

TRINITY-HOUSE, is a kind of college at Deptford, belonging to a company or corporation of seamen, who have authority by the king's charter to take knowledge of those that destroy sea-marks; also to redress the faults of sailors, and divers other things belonging to navigation. Eliz. c. 13. By a late statute, pilots of ships coming up the Thames, are to be examined and approved by the master and wardens of Trinity-house, &c. 3 Geo. 1. c. 13.

TRINITY Sunday, a festival observed on the Sunday next after Whit Sunday, in honour of the holy Trinity. The observation of this festival was first enjoined in the council of Arles, anno 1260.

FRATERNITY OF THE TRINITY, a religious society instituted at Rome by St Philip Neri in 1548. These religious were appointed to take care of the pilgrims who came to visit the tombs of St Peter and St Paul. The society originally consisted of only fifteen religious, who assembled on the first Sunday of every month, in the church of St Saviour del Campo, to hear the exhortations of the founder; after whose death pope Paul IV. gave the fraternity the church of St Bened. near which they have since built a large hospital for the reception of pilgrims. The fraternity is one of the most considerable in Rome, and most of the nobility of both sexes have been members thereof.

TRINOABANTES, (anc. geog.) a people of Britain, supposed to have occupied Middlesex and Essex.

TRIO, in music, a part of a concert wherein three persons sing; or, more properly, a musical composition consisting of three parts.

TRIPHTHONG, in grammar, an assemblage or concurrence of three vowels in one syllable; as, *que*.

TRIPLE, in music, is one of the species of measure or time. See MUSIC.

TRIPOD, in antiquity, a famed sacred seat or stool, supported by three feet, whereon the priests and sybils were placed to render oracles. It was on the tripod that the gods were said to inspire the Pythias

with that divine fury and enthusiasm wherewith they were seized at the delivery of their predictions.

TRIPOLI, a considerable town of Africa, and capital of a republic of the same name in Barbary, and under protection of the grand seignior, with a castle and a fort. It is pretty large, and the inhabitants are noted pirates. It was taken by Charles V. who settled the knights of Rhodes there; but they were driven away by the Turks in 1551. It was formerly very flourishing; and has now some trade in fluffs, saffron, corn, oil, wool, dates, ostrich feathers, and skins; but they make more of the Christian slaves which they take at sea; for they either let high ransoms upon them, or make them perform all sorts of work. It is seated on the coast of the Mediterranean, in a sandy soil, and surrounded by a wall, strengthened by other fortifications. E. Long. 13. 10. N. Lat. 32. 54.

TRIPOLI, a kingdom of Africa, in Barbary; bounded on the north by the Mediterranean sea; on the south, by the country of the Berberes; on the west, by the kingdom of Tunis, Biledulgerid, and a territory of the Gadamis; and on the east, by Egypt. It is about 925 miles along the sea-coast; but the breadth is various. Some parts of it are pretty fruitful; but that towards Egypt is a sandy desert. It had the title of a *kingdom*; but is now a republic, governed by a dey. He is not absolute; for a Turkish bashaw resides here, who receives his authority from the grand seignior, and has a power of controlling the dey, and levying taxes on the people. The dey is elected by the soldiers, who make no scruple of deposing him when he pleases.

TRIPOLI, an ancient and considerable town of Asia, in Syria, on the coast of the Mediterranean sea. The inhabitants are near 60,000, consisting of Turks, Christians, and Jews. There is one very handsome mosque; and all the houses have fountains belonging to them. It is defended by a good citadel, with a garrison of janissaries. This town was anciently in Phoenicia, whose inhabitants were so famous for navigation in the early ages of the world. It is the residence of a bashaw or sangiack, who also governs the territory about it, where there are a great number of mulberry-trees, which enable them to carry on a silk-manufactory in the town. E. Long. 39. 0. N. Lat. 34. 15.

TRIQUETROUS, among botanists, expresses a fruit or leaf that has three sides or faces all flat.

TRIEMIS, in antiquity, a galley with three ranks of oars on a side.

TRISMEGISTUS, an epithet or surname given to one of the two Hermeses. See HERMES.

TRISMUS, the LOCKED JAW. See MEDICINE, n° 388.

TRISSYLLABLE, in grammar, a word consisting of three syllables.

TRITICUM, WHEAT; in botany, a genus of the digynia order, belonging to the triandria class of plants. See AGRICULTURE, n° 112, &c.

TRITON, in zoology, a genus belonging to the order of vermes mollusca. The body is oblong; the tongue is spiral; it has 12 tentacula, six on each side, the hindmost ones having claws like a crab. There is but one species, found in holes of rocks about the shore.

Tripoli
||
Triton.

TRITON, a sea demigod, held by the ancients to be an officer or trumpeter of Neptune, attending on him, and carrying his orders or commands from sea to sea.

TRITURATION, the act of reducing to solid body into a subtille powder; called also *pulverisation* and *levigation*.

TRIUMPH, in Roman antiquity, a public and solemn honour conferred by the Romans on a victorious general by allowing him a magnificent entry in the city.

The greater triumph, called also *curulis*, or simply the *triumph*, was decreed by the senate to a general, upon the conquering of a province or gaining a signal victory. The day appointed for the ceremony being arrived, scaffolds were erected in the forum and circus, and all the other parts of the city where they could best behold the pomp: the senate went to meet the conqueror without the gate called *Capena* or *Triumphalis*, and marched back in order to the capitol; the ways being cleared and cleaned by a number of officers and tipstiffs, who drove away such as thronged the passage or straggled up and down. The general was clad in a rich purple robe, interwoven with figures of gold, setting forth his great exploits; his buskins were beset with pearl; and he wore a crown, which at first was only laurel, but afterwards gold; in one hand he bore a branch of laurel, and in the other a truncheon. He was drawn in a magnificent chariot, adorned with ivory and plates of gold, drawn usually by two white horses; though sometimes by other animals, as that of Pompey, when he triumphed over Africa; by elephants; that of Marc Antony, by lions; that of Helioagalabus, by tygers; that of Aurelian, by deer, &c. His children were at his feet, and sometimes on the chariot-horses. The procession was led up by the musicians, who played triumphal pieces in praise of the general: these were followed by young men, who led the victims to the sacrifice, with their horns gilded, and their heads adorned with ribbands and garlands; next came the carts and waggons, loaded with all the spoils taken from the enemy, with their horses, chariots, &c. these were followed by the kings, princes, and generals, who had been taken captives, loaden with chains: after these appeared the triumphal chariot, before which, as it passed, they all along strewed flowers, and the people with loud acclamations called out, *Io triumph!* The chariot was followed by the senate, clad in white robes; and the senate by such citizens as had been set at liberty or ransomed; and the procession was closed by the priests and their officers and utensils, with a white ox led along for the chief victim. In this order they proceeded through the triumphal gate, along the via sacra, to the capitol, where the victims were slain. In the mean time all the temples were open, and all the altars loaded with offerings and incense; games and combats were celebrated in the public places, and rejoicings appeared every where.

TRIUMVIR, one of three persons who govern absolutely, and with equal authority, in a state. It is chiefly applied to the Roman government: Cæsar, Pompey, and Crassus, were the first triumvirs who divided the government amongst them. There were also other officers so called; as the *triumviri* or *tresviri*

capitales, who were the keepers of the public goal: they had the office of punishing malefactors; for which purpose they kept eight lictors under them.

TROAS, (anc. geog.) a district comprised between the two Mysiæ; and therefore distinct from the kingdom of Troy and the possessions of Priam; and was the Troas Propria; for, according to Homer, both the Mysiæ were under the empire of the Trojans, from the neighbourhood of the river *Ælepus*, and that of Cyziene, to the river *Caycus*, (Strabo); called *Phrygia Minor*, (Ptolemy). Alexandria, a town in this district, was also called *Troas*, a Roman colony.

TROCHANTER, in anatomy. See there n° 37.

TROCHE, in pharmacy, a sort of medicine made of glutinous substances into little cakes, and afterwards exsiccated. See PHARMACY, n° 836—853.

TROCHILUS, the HUMMING-BIRD, a genus belonging to the order of picæ. There are 60 species; all of them remarkable for the beauty of their colours, and most of them for the smallness of their size, though some are eight or nine inches in length.—They are divided into two families, viz. those with crooked bills, and those with straight bills. Of these we shall describe the three following species, from Mr Latham's Synopsis of birds.

1. The little humming-bird has a crooked bill, is an inch and an half in length; frequently weighing less 50 grains. The bill is black, and half an inch in length: the body greenish-brown, with a red, shining, imitable gloss: the head is crested with a small tuft, green at bottom, but of a sparkling gold colour at top: quills and tail fine black. It is a native of Guiana; and the velocity of it in flying is so great, that the eye can scarce keep pace with its motion.

2. The moletinus, or ruby-necked humming-bird, according to Marcgrave is the most beautiful of the whole genus. Its length is three inches four lines: the bill straight, eight lines long, and blackish: the top of the head and hind part of the neck are as bright as a ruby, and of the same colour: the upper parts of the body are brown, with a faint mixture of green gold: the throat and fore part of the neck are the colour of the most brilliant topaz: the belly, sides, and thighs, are brown; but on the lower part of the belly, on each side, is a spot of white: the tail is rufous purple, inclining to violet at the ends; the two middle feathers are shortest: the legs and claws blackish. The female has only a dash of golden or topaz on the breast and fore part of the neck; the rest of the under parts are greyish white. This species is found in Brasil, Curassao, Guiana, and Surinam.

3. The minimus, or least humming-bird, is exceeded, both in weight and dimensions, by several species of bees. The total length is one inch and a quarter: a d when killed, weighs no more, according to Sir Hans Sloane, than 20 grains. The bill is straight and black, three lines and a half in length: the upper parts of the head and body are of a greenish gilded brown, in some lights appearing reddish: the under parts are greyish white; the wings are violet-brown; the tail of a bluish black, with a gloss of polished metal; but the outer feather, except one on each side, is grey from the middle to the tip, and the outer one wholly grey; legs and claws brown. The female is less than the male: the whole upper side of a dirty brown, with a

Slight

Trochilus. flight glossy of green; the under parts of a dirty white. These birds are found in various parts of South America and the adjacent islands.—Our author received it from Jamaica.

These birds subsist on the nectar or sweet juice of flowers: they frequent those most which have a long tube; particularly the *impatiens noli me tangere*, the *monarda* with crimson flowers, and those of the convolvulus tribe. They never settle on the flower during the action of extracting the juice, but flutter continually, like bees, moving their wings very quick, and making a humming noise; whence their name. They are not very shy, suffering people to come within a foot or two of the place where they are, but on approaching nearer fly off like an arrow out of a bow. They often meet and fight for the right to a flower, and this all on the wing: in this state they often come into rooms where the windows stand open, fight a little, and go out again. When they come to a flower which is juiceless, or on the point of withering, they pluck it off as it were in anger, by which means the ground is often quite covered with them. When they fly against each other, they have, besides the humming, a sort of chirping noise like a sparrow or chicken. They do not feed on insects nor fruit; nor can they be kept long in cages, though they have been preserved alive for several weeks together by feeding them with water in which sugar had been dissolved.

This bird most frequently builds in the middle of a branch of a tree, and the nest is so small that it cannot be seen by a person who stands on the ground; any one, therefore, desirous of seeing it, must get up to the branch, that he may view it from above: it is for this reason that the nests are not more frequently found. The nest is in course very small, and quite round: the outside, for the most part, is composed of green moss, common on old pales and trees; the inside of soft down, mostly collected from the leaves of the great mullein, or the silk-grass; but sometimes they vary the texture, making use of flax, hemp, hairs, and other soft materials: they lay two eggs of the size of a pea, which are white, and not bigger at one end than the other.

The above account of the manners will in general suit all the birds of this genus; for as their tongues are made for suction, it is by this method alone that they can gain nourishment: no wonder, therefore, that they can scarcely be kept alive by human artifice. Captain Davies, however, informed our author, that he kept these birds alive for four months by the following method:—He made an exact imitation of some of the tubular flowers with paper, fastened round a tobacco-pipe, and painted them of a proper colour; these were placed in the order of nature, in the cage wherein these little creatures were confined; the bottoms of the tubes were filled with a mixture of brown sugar and water as often as emptied; and he had the pleasure of seeing them perform every action; for they soon grew familiar, and took the nourishment in the same manner as when ranging at large, though close under his eye.

TROGLODITES, in the ancient geography, a people of Ethiopia, said to have lived in caves under ground. Pomponius Mela gives a strange account of the Troglodites: he says, they did not so properly speak as shriek; and that they lived on serpents. They are ranked by Linnaeus with mankind; (see *Homo*.)

But we have given their character and natural history under *SMIA*, among their proper companions. See that article.

TROGUS (Pompeius), Latin universal historian to the time of Augustus Cæsar, of whom we have only an abridgement by Justin, flourished about 41. B. C.

TROIA (anc. geog.), a celebrated name denoting a district, at first called *Idea*; and the city, *Ilium*. But the custom has prevailed to call both district and city *Troia*; and this last more commonly *Troia* than *Ilium*, and both with the epithet *Vetus*. Trojans, the people; often called *Phryges*, (V. rel.); and *Troes*, from Tros, (Stephanus); *Trojanus*, *Troius*, and *Phrygius*, the epithets, (Virgil); *Troicus*, (Ovid). Whether the Phrygians before the Trojan times, or after the destruction of Troy, occupied that country, is hard to determine in such a distant antiquity.

TROIS RIVIERES, a town of North America, in the province of Canada, situated on the river S. Lawrence, 50 miles south of Quebec. W. Long. 75° N. Lat. 46. 45.

TROLLIUS, the *GLOBE FLOWER*, or *Lucken Gowan*; a genus of the polygænia order, belonging to the polyandria class of plants. There are two species; of which the most remarkable is the europæan, a native of the northern countries of Europe. The leaves are divided first into five segments down to the base; the segments are again divided, each about half way, into two or three lobes, which are sharply indented on the edges. The stalk is a foot high, and scarcely branched: the flower is yellow, globose, and speciosus. It grows at the foot of mountain, and by the sides of rivulets. The country people in Sweden strew their floors and pavements on holidays with the flowers, which have a pleasant smell, and are ornamental in gardens.

TROMP (Martin Happeriz Van), a celebrated Dutch admiral, was born at the Bille, in Holland. He raised himself by his merit, after having distinguished himself on many occasions, especially at the famous engagement near Gibraltar in 1607. He passed for one of the greatest seamen that had till that time appeared in the world; and was declared admiral of Holland, even by the advice of the prince of Orange. He in that character defeated a large Spanish fleet in 1630, and gained 32 other victories at sea; but was killed when under deck, in an engagement with the English in 1653 †. The states general caused medals to be struck to his honour, and lamented him as one of the greatest heroes of their republic. Van Tromp, in the midst of the greatest glory, constantly discovered a remarkable modesty; for he never assumed a higher character than that of a burgher, and that of being the father of the sailors.

TRONAGE, an ancient customary duty, or toll, for weighing of wool. According to Fleta, *trona* is a beam to weigh with, mentioned in the Stat. Westm. 2. cap. 25. And tronage was used for the weighing wool in a staple or public mart, by a common trona or beam; which, for the tronage of wool in London, was fixed at Leadon-Hall. The mayor and commonalty of London are ordained keepers of the beams and weights for weighing merchants commodities, with power to assign clerks, and porters, &c. of the great beam and balance; which weighing of goods and wares is called

tronage;

Trogus
Tronage.

† See Brit-
tain, 10174.

Trone
Troiter

trouage: no stranger shall buy any goods in London before they are weighed at the king's beam, on pain of forfeiture.

TRONE WEIGHT, the most ancient of the different weights used in Scotland; and, tho' now forbidden by several statutes, is still used by many for home-commodities, and that in a very irregular manner; for the pound varies in different places, and for different purposes, from 20 to 24 Dutch ounces. The common allowance is 2½ oz. for wool, 20½ for butter and cheese, 20 for tallow, lint, hemp, and hay. It is divided into 16 of its own ounces, and 16 pounds make a stone.

TROOP, a small body of horse or dragoons, about 50 or 60, sometimes more, sometimes less, commanded by a captain, lieutenant, cornet, quarter-master, and three corporals, who are the lowest officers of a troop.

TROPE. See **ORATORY**, n° 49—59.

TROPHIUM ANTRUM or Oraculum, (anc. geog.), a cave near Lebada in Boeotia, between Helicon and Charonea; (Strabo): so called from Trophonius, an enthusiastic diviner; who, descending into this cave, pretended to give answers and pronounce oracles; and was hence called *Jupiter Trophonius*. Such as went down to this cave never after smiled; hence the proverbial saying of a man who has lost his mirth, That he is come out of Trophonius's cave. Though Pausanias, who writes from experience, contradicts this; affirming that persons came out of the cave affected indeed with a stupor, but that they soon after recover themselves.

TROPHY, (*Trophaum*), among the ancients, a monument of victory. As the term, so the custom is of Greek original. At first it only consisted of the trunk of a tree, lopped of its branches, fixed in the earth on an eminence, and adorned with the armour taken from the enemy, (Virgil.) Afterwards the trophies were pillars of brass or stone; but such were in disrepute among the Greeks, as serving to perpetuate contention, which ought to be buried in oblivion, (Plutarch.) They were accounted inviolable; none was to remove or destroy them; but, if consumed by length of time, it was thought an invidious act and a renewal of grudge to restore them. On every trophy there was an inscription, setting forth the cause of the war, and manner of the victory; with an account of the spoils with which they were adorned. Some of the spoils taken from the enemy were also hung up in the temples; and these too were called *trophies* and *anathemata*, because suspended or hung up in view.

TROPICS, in astronomy. See there n° 110, & seq.

TROS, king of Tencria, founder of the ancient city of Troy, and after whose name his subjects took the appellation of Trojans, flourished about 1334 B. C.

TROTTER (Mrs Catharine), was the daughter of captain David Trotter, a Scots gentleman. He was a commander in the royal navy in the reign of Chas. II. and at his death left two daughters, the youngest of whom, Catharine, our celebrated author, was born in London, August 1679. She gave early marks of her genius; and learned to write, and also made herself mistress of the French language, by her own application and diligence, without any instructor; but she had some assistance in the study of the Latin grammar and logic, of which latter she drew up an abstract for her own use. The most serious and important subjects,

Trotter

and especially religion, soon engaged her attention. — But notwithstanding her education, her intimacy with several families of distinction of the Romish persuasion, exposed her, while very young, to impressions in favour of that church; which not being removed by her conferences with some eminent and learned members of the church of England, she embraced the Romish communion, in which she continued till the year 1707. In 1695, she produced a tragedy called *Agnès de Castro*, which was acted at the theatre-royal when she was only in her 17th year. The reputation of this performance, and the verses which she addressed to Mr Congreve upon his *Mourning Bride* in 1697, were probably the foundation of her acquaintance with that celebrated writer. Her second tragedy, *Fatal Friendship*, was acted in 1698, at the new theatre in Lincoln's Inn-Fields. This tragedy met with great applause, and is still thought the most perfect of her dramatic performances. Her dramatic talents not being confined to tragedy, she brought upon the stage, in 1701, a comedy called *Love at a loss*, or *Most votes carry it*. In the same year she gave the public her third tragedy, entitled the *Unhappy Penitent*, acted at the theatre-royal in Drury-lane. But poetry and dramatic writing did not so far engross the thoughts of our author but that she sometimes turned them to subjects of a very different nature; and distinguished herself in an extraordinary manner in defence of Mr Locke's writings, a female metaphysician being a remarkable phenomenon in the republic of letters.

She returned to the exercise of her dramatic genius in 1703, and fixed upon the revolution of Sweden, under Gustavus Erickson, for the subject of a tragedy. This tragedy was acted in 1706, at the queen's theatre in the Hay-Market. In 1707, her doubts concerning the Romish religion, which she had for many years professed, having led her to a thorough examination of the grounds of it, by consulting the best books on both sides of the question, and advising with men of the best judgment, the result was a conviction of the fallaciousness of the pretensions of that church, and a return to that of England, to which she adhered during the remainder of her life. In 1708, she was married to the Rev. Mr Cockburn, then curate of St Dunstan's in Fleet-street, but he afterwards obtained the living of Long-Horsely, near Morpeth in Northumberland. He was a man of considerable abilities; and, among several other things, wrote an account of the Mosiac Deluge, which was much approved by the learned.

Mrs Cockburn's remarks upon some writers in the controversy concerning the foundation of moral duty and moral obligation, were introduced to the world in August 1743, in the *Literary Journal*, intitled *The History of the Works of the Learned*. The strength, clearness, and vivacity shown in her remarks upon the most abstract and perplexed questions, immediately raised the curiosity of all good judges about the concealed writer; and their admiration was greatly increased when her sex and advanced age were known. Dr Butler's *Essay on the Nature and Obligations of Virtue*, published in May 1744, soon engaged her thoughts; and notwithstanding the ailment disorder which had seized her many years before, and now left her small intervals of ease, she applied herself to the confutation of that elaborate discourse, and finished it with

Trotter
||
Truiss.

with a spirit, elegance, and perspicuity equal, if not superior, to all her former writings.

The loss of her husband in 1748, in the 71st year of his age, was a severe shock to her; and she did not long survive him, dying on the 11th of May 1749, in her 71st year, after having long supported a painful disorder with a resignation to the Divine will, which had been the governing principle of her whole life, and her support under the various trials of it.

Her works are collected into two large volumes 8vo., by Dr Birch; who has prefixed to them an account of her Life and Writings.

TROUBADOURS. See POETS *Provençal*.

TROVER, in law, an action that a man hath against one that, having found any of his goods, refuseth to deliver them upon demand.

TROY. See *TROIA*.

Troy-Weight, the most ancient of the different kinds used in Britain. The ounce of this weight was brought from Grand Cairo in Egypt, about the time of the crusades, into Europe, and first adopted in *Troyes*, a city of Champagne; whence the name.

The pound *English* Troy contains 12 ounces, or 5760 grains. It was formerly used for every purpose; and is still retained for weighing gold, silver, and jewels; for compounding medicines; for experiments in natural philosophy; and for comparing different weights with each other.

Scott's Troy Weight was established by James VI. in the year 1618, who enacted, that only one weight should be used in Scotland, viz. the French Troy stone of 16 pounds, and 16 ounces in the pound. The pound contains 7600 grains, and is equal to 17 oz. 6 dr. averdupois. The cwt. or 112 lb. averdupois, contains only 103 lb. 2½ oz. of this weight, though generally reckoned equal to 104 lb. This weight is nearly, if not exactly, the same as that of Paris and Amsterdam; and is generally known by the name of *Dutch weights*. Though prohibited by the articles of union, it is still used in weighing iron, hemp, flax, most Dutch and Baltic goods, meal, butcher-meat, unwrought pewter and lead, and some other articles.

TRUFFLES. See LYCOPERDON.

TRUMPET, a musical instrument, the most noble of all the wind-kind, used chiefly in war among the cavalry, to direct them in the service.

Speaking TRUMPET. See ACOUSTICS, n° 26.

TRUNCATED, in general, is an appellation given to such things as have, or seem to have, their points cut off: thus we say, a truncated cone, pyramid, leaf, &c.

TRUNCHEON, a short staff or baton, used by kings, generals, and great officers, as a mark of their command.

TRUNDLE, a sort of carriage with low wheels, whereon heavy and cumbersome burdens are drawn.

TRUNK, among botanists, that part of the herb which arises immediately from the root, and is terminated by fructification; the leaves, buds, and auxiliary parts of the herb not entering in its description.

TRUNNIONS, or TAUNIONS, of a piece of ordnance, are those knobs or bunches of the metal which bear her up on the cheeks of the carriage.

TRUSS, a bundle, or certain quantity of hay, straw,

&c. A truss of hay is to contain 56 pounds, or half an hundred weight: 36 trusses make a load.

TRUSS is also used for a sort of bandage or ligature made of steel, or the like matter, wherewith to keep up the parts in those who have hernias or ruptures.

TRUSS, in a ship, a machine employed to pull a yard home to its respective mast, and retain it firmly in that position.

TRUSTEE, one who has an estate, or money, put or trusted in his hands for the use of another.

TRUTH, a term used in opposition to falsehood, and applied to propositions which answer or accord to the nature and reality of the thing whereof something is affirmed or denied. See METAPHYSICS, n° 214, &c.

TRYPHIODORUS, an ancient Greek poet, who lived some time between the reigns of Severus and Anastasius. His writings were very numerous; yet none of them have come down to us, except an epic poem, on which Mr Addison has made some entertaining remarks in the *Spectator*, N° 63. Treating of the several species of false wit among the ancients, he mentions the *lipogrammatists*, or letter-droppers of antiquity, and adds, "One Tryphiodorus was a great master in this kind of writing. He composed an *Odyssæ*, or epic poem, on the adventures of Ulysses, consisting of 24 books, having entirely banished the letter A from his first book, which was called *Alpha*; as *lucus à non lucendo*, because there was not an alpha in it. His second book was inscribed *Beta* for the same reason. In short, the poet excluded the whole 24 letters in their turns; and showed them, one after another, that he could do his business without them. It must have been very pleasant to have seen this poet avoiding the reprobate letter as much as another would a false quantity; and making his escape from it thro' the several Greek dialects, when he was pressed with it in any particular syllable: for the most apt and elegant word in the whole language was rejected, like a diamond with a flaw in it, if it appeared blemished with a wrong letter."

The first edition of this extraordinary work was published by Aldus, at Venice, with Quintus Calaber's *Paralipomena*, and Coluthus's poem on the rape of Helen. It has been since reprinted at several places, particularly at Francfort in 1580 by Frischlinus; who not only corrected many corrupt passages, but added two Latin versions, one in verse, and the other in prose. That in verse was reprinted in 1742, with the Greek, at Oxford, in 8vo, with an English translation in verse, and Notes, by Mr Merrick.

TUAM, a town of Ireland, in the province of Connaught, and county of Galway, with an archbishop's see. It was once a famous city, though now it is reduced to a village; yet it still retains the title of a city, as being an archiepiscopal see. It is seven miles from the borders of Mayo. W. Long. 9. o. N. Lat. 53. 25.

TUB, in commerce, denotes an indetermined quantity or measure: thus, a tub of tea contains about 60 pounds; and a tub of camphor from 56 to 80 pounds.

TUBAL CAIN, the son of Lamech and Sella, was born about the 2975th year before the Christian æra. He invented the art of working in brass, iron, and other metals; and many have imagined that from him the pagan authors took the idea of their Vulcan.

TUBE,

Tubis
||
Tubal.

TUBE, in general, a pipe, conduit, or canal; a cylinder, hollow within-side, either of lead, iron, glass, wood, or other matter, for the air or some other matter to have a free conveyance through it.

Auricular Tube, or instrument to facilitate hearing. See **Acoustics**, n° 26.

TUBERCLES, among physicians, denote little tumours which suppurate and discharge pus; and are often found in the lungs, especially of consumptive persons.

TUCUMAN, a province of South America, in Paraguay; bounded on the north by the provinces of Los-Chicas and Chaco; on the east by Chaco and Rio-de-la-Plata, on the south by the country of Chichitos and Pampas, and on the west by the bishopric of St Jago. The air is hot, and the earth sandy; however, some places are fruitful enough, and the original natives have a good character. The Spaniards possess a great part of this country.

TUFO, a kind of stone, according to M. Raspe, formed of volcanic ashes ferruginated and concreted together. It is of various colours; blackish-grey, bluish-grey, and yellow; every colour having a different mixture and solidity: but all of them have the bad quality of mouldering down on long exposure to the weather; notwithstanding which, they have been used in buildings both ancient and modern. The yellow kind reflects the air less than any other.

TULIPA, the **TULIP**; a genus of the monogynia order, belonging to the hexandria class of plants. There are three species, two of which only are known in the English gardens; and one of these in particular (the first sort) is famous for the extraordinary beauty of its large noble flowers, most elegantly striped and stained with a vast diversity of rich colours, in a thousand various forms; constituting so many different varieties, all very great ornaments to our gardens in April and May.

1. The *gesneriana*, Gesner's Turkey tulip of Cappadocia, or common garden-tulip, hath a large, oblong, truncated, solid, bulbous root, covered with a brown skin, sending up long oval spear-shaped leaves; an upright round stalk, from half a foot to a yard high, garnished with a few leaves, and its top crowned with a large bell-shaped erect hexapetalous flower, of almost all colours and variegations in the different varieties.

The principal varieties are, early dwarf tulip (*præcocæ*), rising with short stalks, from five or six to 10 or 12 inches high, with smallish flowers.—Tall late-flowering or common tulip (*serotina*), rising from about half a yard to two or three feet high, with large well-formed flowers.—Double tulip, rising a foot or two high, or more, having large double flowers.—Whole-blowing, or self coloured tulip, being all of one original colour, either purples, reds, violets, greys, copper-colours, yellows, &c. which gradually break into numerous variegations.—Variegated tulip, comprising innumerable varieties, in respect to the different colourings, variegations, and stripes.

Each of the above varieties comprehends numerous intermediate ones, in respect to the colours and variegations of the flower; each, however, is originally all of one colour, especially seedlings, which, when arrived to a flowering state, each separate flower is either wholly red, purple, violet, grey, brown, black, or yellow.

low, &c. without any variegations or stripes, consisting of self-coloured flowers with white bottoms; self-coloured flowers with yellow bottoms; and some also with blue, purple, and blackish bottoms; all of which, whilst they retain this original same colour, are in the florists language called *suble blowers* or *breakers*, because each flower is wholly of one self-colour. The roots being planted a year or two in prepared soils, to breed, or dispose them gradually to produce flowers that break from the original self-colour into variegations and stripes in various different forms, they are then called *breakers*, each different variegation constituting a distinct variety; consisting of flowers with—white bottoms, broken with brown stripes, with blue stripes, violet stripes, rose stripes, red stripes, &c. separated by streaks of white and other colours, variously disposed—yellow bottoms, broken with different reds, crimsons, and golden-yellow flakes, and various other colours—blackish purple bottoms, &c. broken with stripes of dark colour, yellow, and tints of red: so that in these sorts of breakers, or variegated tulips, with white and yellow bottoms particularly, there are also white and red striped flowers—white and purple striped—white and violet striped—white and rose striped—white and brown striped—violet and white flaked—red and white flaked—red and yellow flaked—brown, yellow, and red flaked and numerous other intermediate variegations and stripes, variously disposed in an endless diversity.

Thus the breakers or variegated tulips are diversified with an infinity of colours in innumerable different ways, forming so many different varieties; the principal of which are by the florists distinguished by pompous names, either of some great personages, eminent florists, places of their original growth, &c.: but as vast numbers of new varieties are annually obtained from seedlings in so many different places, distinguished by various new names, and old ones rejected, and often the same flower, with a different name imposed by different florists, it would be impossible to give any correct list here of the names of such numerous varieties, so often changing every where.

2. The *silvestris*, or wild European tulip, hath an oblong bulbous root, sending up long narrow spear-shaped leaves; and a slender stalk, supporting at top a small yellow flower, nodding on one side, having acute petals.

Both these species of tulipa are hardy perennials, durable in root, or at least, altho' the old bulb decays annually, it perpetuates its species by off-sets, and is annual in leaf and stalk; which rising from the bulb early in the spring, arrives to a flowering state in April and May, each plant having only one flower, supported on the top of the naked stalk without any calix or cup, and consists of six large petals, three within and three without, mostly in an erect position; the whole together forming a sort of large cup, either bell or egg shaped, though the double tulip have the petals multiplied in an indeterminate number. All the varieties are succeeded by plenty of ripe seed in July and August, contained in an oblong capsule of three cells, having the seeds placed on each other in double rows. By the seeds numerous new varieties may be raised, which however will not attain a flowering state till they are seven or eight years old; and after that will require

Tulipa. two or three years or more to break into variegations, when the approved varieties may be marked, and increased by off-sets of the root, as directed in their propagation.

Of the two species of tulip, the first sort, *Tulipa gesneriana*, or common garden-tulip, and its vast train of varieties, is the sort so generally cultivated for the ornament of our gardens, and so much admired by all for its great variety and beautiful appearance: It grows freely in the open ground in any common soil of a garden, and proves a very great decoration to the beds and borders of the pleasure-ground, for six weeks or two months in spring, by different plantings of early and late sorts; planting the principal part in autumn, and the rest towards Christmas, and in January or February. The autumn plantings will come earliest into bloom, and flower the strongest; and the others will succeed them in flowering; observing, that in summer, when the flowering is past, and the leaves and stalks assume a state of decay, the bulbs of the choicest varieties are generally taken up, the off-sets separated, and the whole cleaned from filth; then put up to dry till October or November, and then planted again for the future year's bloom.

Of this species, which is the florist's delight, the varieties may be divided into two principal classes, viz. 1. Early or dwarf spring-tulips (*præcocea*). 2. Late-flowering tall tulips (*ferotina*).

Early tulips.—The early tulips are among florists distinguished by the appellation of *præcocea* (early), because they flower early in the spring, a month or more before the others; are much shorter stalked, and the flowers smaller; but are in greater reputation for their early bloom and their gay lively colours, both of self-colours, and broken into flaked variegations; such as reds, crimson, scarlet, carnation, violets, purples, yellow, &c. with flowers of each, edged and flaked with red, yellow, and white, in many diversities.

Late-flowering common tulips.—This class is denominated *late flowering*, and by the florists called *ferotines*, because they blow later in the spring, a month or more, than the *præcocea*, i. e. not coming into flower before the end of April, May, and June. They are all of tall growth, supporting large flowers, and furnish an almost endless variety in the vast diversity of colours, after they break from whole-blowers into variegations and stripes, exceeding all others of the tulip kind in beauty and elegance of flower.

Tulips are also subdivided into other classes, such as whole blowers, and broken tulips.

Whole blowers or breeders.—These are seedling tulips, having flowers wholly of one colour; they being raised from seed to a state of flowering, the flowers remain two, three, or more years of one self-colour, before they break into variegations; which are also divided into classes, according to the Dutch florists, called,—1. *Bizarres*; being generally almost of a brown copper colour, having at the bottom a small round spot, either yellowish, or black mixed with a little yellow, which when broken into different colours become *bizarres* with yellow bottoms.—2. *Violettes*; being either all of purple-violet, pale violet, grideline, cherry-crimson, or red; having the spot at bottom, either a clear white, or black sh-grey mixed with a little white; and their production when broken into different colours be-

come tulips with white bottoms, called by the Dutch *bybloemen*.

Broken or variegated tulips.—Such as are broken from the self original colour of the whole-blower or breeding tulips, into variegations and stripes of different colours, observing they generally break into different variegations according to that of the former self-colour; generally, however, either wholly expelling the original self-colour of the breeder, or leave but very little remains thereof, which is a desirable requisite in these kind of flowers among professed florists; and, when thus broken or variegated with different colours, they exhibit themselves variously mixed, striped, flaked, feathered, marbled, spotted, edged, &c. a thousand different ways in an admirable manner; and are by the florists divided into the following classes, called by the Dutch

Baguette primo.—Tulips with white bottoms, striped with brown, &c.

Baguette rigau.—Tulips with a white bottom, broken with dark-brown stripes, &c.

Bybloemen.—Tulips with a white bottom, striped with violet and blackish brown, &c. White bottom tulips, striped with rose-colour, vermilion, and ruby.

Bizarres.—Yellow bottom tulips, striped with various colours.

Among florists the principal properties requisite in the above classes of tulips to constitute a fine flower, are—The stem must be tall, especially of the *ferotines*, from half a yard to two or three feet high, or more, being proportionably thick and strong; the flower large, composed of six petals, as in the characteristic state, these being broad, thick, rounded at top, and stand firmly erect without turning much inward or outward, but so as to cup well, and give the flower a regular form. The colours and stripes of the flower must be bright, arising unmixed, regularly and distinct from the bottom, with but little or none of the original self-colour remaining.

The colours in greatest estimation in the broken tulips, are the blacks, golden-yellows, purple-violets, rose, and vermilion, each of which being variegated various ways; and such as are striped with three different colours distinct and unmixed, with strong regular streaks, with but little or no tinge of the breeder, may be called the most perfect tulips. Though it is rare to meet with a tulip possessing all the properties.

As to the manner of obtaining this wonderful variety of colours in tulips, it is often accomplished principally by nature alone, which however is sometimes assisted and forwarded by some simple operations of art; such as, that in the first place, when the seedling bulbs of the whole blower or breeder are arrived to full size, and have flowered once, to transplant them into beds of any poor dry barren soil, in order that by a defect of nutriment in the earth the natural luxuriance of the plant may be checked, and cause a weakness in their general growth, whereby they generally in this weakened or infirm state gradually change and break out into variegations, some the first year, others not till the second or third; and according as they are thus broke, they should be planted in beds of good earth.

Another method to assist nature in effecting the marvellous work of breaking the breeding tulips into diversified colours, is to make as great a change as possible

Tulipa
Tun.

sible in the soil; if they were this year in a light poor soil, plant them the next in a rich garden mould, and another year in a compost of different earths and dung; or transplant them from one part of the garden to another, or into different gardens, &c. or from one country to another; all of which contributes in affixing nature in producing this desirable diversity of colours and variegations.

The double tulip is also a variety of the common tulip, and is very beautiful, tho' not in such estimation among the florists as the common single variegated sorts, not possessing such a profusion of variegations in the colours and regularity of stripes: they however exhibit an elegantly ornamental appearance, as they rise with an upright, tallish, firm stem, crowned with a very large double flower composed of numerous petals, multiplied in several series one within another like a double peony, but far more beautiful in their diversity of colours, variegations, and stripes of white and red, yellow and red, &c. so that they highly deserve culture, both in beds alone near the other sorts to increase their variety, also to plant in patches about the borders, in assemblage with the late variegated tulips, as they blow nearly about the same time, *i. e.* April and May.

Tulip-roots are sold in full collection, consisting of numerous varieties, at most of the nurseries and seedsmen, who both propagate them themselves by off-sets and seed; and import vast quantities annually from Holland; the Dutch being famous for raising the grandest collections of the finest tulips, and other bulbous flowers, in the greatest perfection, for the supply of almost all the other European gardens; distinguishing every variety in their vast collections by some pompous name or other, as before observed, arranged in regular catalogues, charging prices in proportion to their estimation; which formerly was so great, among the Hollanders themselves in particular, that there are accounts of a single root being sold for from 2000 to 5500 guilders; however, they are now more plentiful, and are sold at from 5s. or 10s. to 50 many pounds *per* hundred, and even *per* root for very scarce capital sorts.

TULIP Tree. See LIRIODENDRON.

TULL (Jethro), an Oxfordshire gentleman who farmed his own land, and introduced a new method of culture, to raise repeated crops of wheat from the same land without the necessity of manure; the principles of which he published about 30 years since, in *A Treatise on Horse-hoeing Husbandry*. See AGRICULTURE.

TUMBRELL, TUMBRELLUM, or *Turbichetum*, is an engine of punishment, which ought to be in every liberty that hath the view of frank-pledge, for the correction of scolds and unquiet women.

TUMEFACATION, the act of swelling or rising into a tumour.

TUMOUR, in medicine and surgery, a preternatural rising or eminence in any part of the body.

TUMOURS, in farrery. See there, § xxiv.

TUN, a large vessel or cask, of an oblong form, biggest in the middle, and diminishing towards its two ends, girt about with hoops, and used for stowing several kinds of merchandise for convenience of carriage; as brandy, oil, sugar, skins, hats, &c.

TUN is also the name of a measure. A tun of wine is four hogheads; of timber, a square of 40 solid feet;

and of coals, 20 Cwt.

TUN is also a certain weight whereby the burden of ships, &c. are estimated. See SHIP.

TUNBRIDGE, a town of Kent in England, situated on a branch of the river Medway, over which there is a bridge. It is a large well built place, noted for the mineral waters four or five miles south of the town. E. Long. *o.* 16. N. Lat. 54. 14.

TUNICA, a kind of waistcoat or under garment, in use among the Romans. They wore it within doors by itself, and abroad under the gown. The common people could not afford the toga, and so went in their tunics; whence Horace calls them *populus tunicalus*.

TUNICA, in anatomy, is applied to the membranes which invest the vessels, and divers others of the less solid parts of the body; thus the intestines are formed of five tunics or coats.

TUNIS, a large and celebrated town of Africa, in Barbary, and capital of a kingdom of the same name. It is seated on the point of the Gulph of Goletta, about eight miles from the place where the city of Carthage stood. It is in the form of a long square, and is five miles in circumference, with 10 large streets, 5 gates, and 35 mosques. The houses are all built with stone, though but one story high; but the walls are very lofty, and flanked with several strong towers. It has neither ditches nor bastions, but a good citadel, built on an eminence on the west side of the city. Without the walls are two suburbs, which contain 1000 houses. Within the walls are 10,000 families, and above 3000 tradesmen's shops. The divan, or council of state, assembles in an old palace; and the dey is the chief of the republic, who resides there. The harbour of Tunis has a very narrow entrance, through a small canal. In the city they have no water but what is kept in cisterns, except one well kept for the bashaw's use. It is a place of great trade, and is 10 miles from the sea. E. Long. 10. 51. N. Lat. 36. 40.

TUNIS, a kingdom of Africa, bounded on the north-east by the Mediterranean Sea and the kingdom of Tripoli; on the south by several tribes of the Arabs, and on the west by the kingdom of Algiers and the country of Esab; being 300 miles in length from east to west, and 250 in breadth from north to south. This country was formerly a monarchy; but a difference arising between the father and son, one of which was for the protection of the Christians, and the other for that of the Turks, in 1574 the inhabitants shook off the yoke of both. From this time it became a republic under the protection of the Turks, and pays a certain tribute to the bashaw who resides at Tunis. The air in general is healthy; but the soil in the eastern parts is indifferent for want of water. Towards the middle the mountains and valleys abound in fruits; but the western part is the most fertile, because it is watered with rivers. The environs of Tunis are very dry, upon which account corn is generally dear. The inroads of the Arabs oblige the inhabitants to sow their barley and rye in the suburbs, and to inclose their gardens with walls. However, there are plenty of citrons, lemons, oranges, dates, grapes, and other fruits. There are also olive-trees, roses, and odoriferous plants. In the woods and mountains there are lions, wild bees, ostriches, monkeys, camels, roe-bucks, hares, pheasants, partridges, and other sorts of birds and beasts.

Tun
Tunis.

Tunnage
Turbo.

The most remarkable rivers are the Guadalcarbar, Magrida, Mageracla, and Caps. The form of government is aristocratic; that is, by a council, whose president is the dey, not unlike the doge of Venice. The members of the divan or council are chosen by the dey, and he in his turn is elected by the divan; which is composed of soldiers, who have more than once taken off the dey's head. The bashaw is a Turk, residing at Tunis; whose business is to receive the tribute, and protect the republic: the common revenues are only 400,000 crowns a-year, because the people are very poor; nor can they send above 40,000 men into the field; nor no more than 12 men of war of the line to sea, even upon the most extraordinary occasions. There are generally about 12,000 Christian slaves in this country; and the inhabitants carry on a great trade in linen and woollen cloth. In the city of Tunis alone, there are above 3000 clothiers and weavers. They also have a trade in horses, olives, oil, soap, ostriches eggs and feathers. The Mahometans of this city have nine colleges for students, and 86 petty schools. The principal religion is Mahometanism; but the inhabitants consist of Moors, Turks, Arabs, Jews, and Christian slaves. However, the Turks, though fewest in number, domineer over the Moors, and treat them little better than slaves.

TUNNAGE. See TONNAGE.

TUNNY, in ichthyology. See SCOMBER.

TURBAN, the head-dress of most of the eastern nations. It consists of two parts, a cap and a shawl of fine linen or taffety, artfully wound in divers plaits about the cap. The cap has no brim, is pretty flat, though roundish at top, and quilted with cotton; but does not cover the ears. There is a good deal of art in giving the turban a fine air; and the making of them is a particular trade. The shawl of the Turks turban is white linen; that of the Persians red woollen. These are the distinguishing marks of their different religions. Sophi king of Persia, being of the sect of Ali, was the first who assumed the red colour, to distinguish himself from the Turks, who are of the sect of Omar, and whom the Persians esteem heretics.

TURBINATED, is a term applied by naturalists to shells which are spiral or wreathed conically, from a larger basis to a kind of apex.

TURBITH, or TURPETH-Root, in the materia medica, the cortical part of the root of a species of convolvulus. See CONVOLVULUS.

TURBITH Mineral. See CHEMISTRY, n° 154.

TURBO, the WREATH, in zoology, a genus of insects belonging to the order of vermes testacea. The animal is of the snail kind; the shell consists of one spiral solid valve, and the aperture is orbicular. There are 49 species; of which the most remarkable are, 1. The littoreus, or periwinkle. This is abundant on moist rocks far above low-water mark. The Swedish peasants believe that when these shells creep high up the rocks, they indicate a storm from the south. They are eaten by the poor people in most parts of this kingdom. Young lobsters are said to take up their lodging in the empty shells of these animals, which has given occasion to a notion that periwinkles are changed into lobsters. 2. The clathrus, or barbed wreath, has a taper shell of eight spires, distinguished by elevated divisions running from the aperture to the apex. There

is a variety pellucid, with very thin edges. It is analogous to that curious and expensive shell, the *ventile-trap*.

TUREDOT, in ichthyology. See PLEURONECTES.

TURCÆ, or TURCI, (Mela); supposed to be the *Tufci* of Ptolemy; whom he places between Caucasus and the Montes Ceraunii. The name is said to denote, "to desolate, or lay waste." Herodotus places them among the wild or barbarous nations of the north. There is a very rapid river called *Turk*, running into the Caspian Sea, from which some suppose the Turks to take their name. They made no figure in the world till towards the 7th century; about the beginning of which they sallied forth from the Portæ Caspiæ, laid waste Persia, and joined the Romans against Chosroes king of Persia. In 1042, they subdued the Persians, in whose pay they served, and from whom they derived the Mahometan religion; and afterwards pouring forth, over ran Syria, Cappadocia, and the other countries of the Hither Asia, under distinct heads or princes, whom Ottoman subduing, united the whole power in himself, which to this day continues in his family, and who fixed his seat of empire at Prusa in Bithynia. His successors subdued all Greece, and at length took Constantinople in 1453; which put a period to the Roman empire in the East, under Constantine the last emperor. It is a standing tradition or prophecy among the Turks, that their empire will at length be overturned by the Franks or Christians; which seems now to be drawing on apace towards accomplishment.

TURCICA TERRA, *Turkey-Earth*, a very fine bole dug in great quantities in the neighbourhood of Adrianople, used by the Turks as a sudorific and astringent, and famous among them in pestilential diseases.

TURCOISE, in natural history, an ore of copper. There are indeed two kinds of turcoises; the one a true and genuine ore of copper, and the other the bones of animals tinged to a beautiful blue colour by having been buried in places where copper ore has been near them.

TURCOMANIA, a province of Asiatic Turkey, answering to the ancient kingdom of Armenia.

TURDUS, the THRUSH; a genus of birds belonging to the order of passeræ. The bill is somewhat cylindrical and cultrated; the nostrils are naked; the fauces is ciliated; and the tongue is lacerated. There are 28 species, the most remarkable of which are,

1. The visivorus, or the mistle, is the largest of the genus. Its length is 11 inches; its breadth 16½. The bill is shorter and thicker than that of other thrushes; dusky, except the base of the lower mandible, which is yellow. The irides are hazel. Head, back, and lesser coverts of the wings, are of a deep olive brown. The lower part of the back is tinged with yellow. The lowest order of lesser coverts, and the great coverts, are brown; the first tipped with white, the last both tipped and edged with the same colour. The inner coverts of the wings white. The tail is brown; the three outermost feathers tipped with white. The cheeks and throat are mottled with brown and white; the breast and belly are whitish yellow, marked with large spots of black; the legs are yellow.

These birds build their nests in bushes, or on the side of some tree, generally an ash, and lay four or five eggs; their note of anger or fear is very harsh, be-

Turbot
Turdus.

tween a chatter and skrick; from whence some of its English names. Its song, however, is very fine; which it begins sitting on the summit of a high tree, very early in the spring, often with the new year, in blowing showery weather, which makes the inhabitants of Hampshire to call it the *storm-cock*. It feeds on insects, holly and mistletoe berries, which are the food of all the thrush kind: in severe snowy weather, when there is a failure of their usual diet, they are observed to scratch out of the banks of hedges, the root of arum, or the cuckoo pint; this is remarkably warm and pungent, and a provision suitable to the season.

2. The *pilaris*, or fieldfare, is in length 10 inches, in breadth 17. The head is ash-coloured inclining to olive, and spotted with black; the back and greater coverts of the wings of a fine deep chestnut; the tail is black; the lower parts of the two middlemost feathers, and the interior upper sides of the outmost feathers excepted; the first being ash-coloured, the latter white. The legs are black; the talons very strong.

This bird passes the summer in the northern parts of Europe; also in lower Austria. It breeds in the largest trees; feeds on berries of all kinds, and is very fond of those of the juniper. Fieldfares visit our islands in great flocks about Michaelmas, and leave us the latter end of February or the beginning of March.

These birds and the redwings were the *turdi* of the Romans, which they fattened with crumbs of figs and bread mixed together. Varro informs us that they were birds of passage, coming in autumn, and departing in the spring. They must have been taken in great numbers; for, according to Varro (lib. 3. c. 5.) they were kept by thousands together in their fattening aviaries. They do not arrive in France till the beginning of December.

3. The *musculus*, or thrush, is in length 9 inches, in breadth 13½. In colours it so nearly resembles the mistle-thrush, that no other remark need be added, but that it is less, and that the inner coverts of the wings are yellow.

The thrush is the finest of our singing birds, not only for the sweetness and variety of its notes, but for the long continuance of its harmony; for it obliges us with its song for near three parts of the year. Like the mistle-bird, it delivers its music from the top of some high tree; but to form its nest defends to some low bush or thicket: the nest is made of earth, moss, and straw, and the inside is curiously plastered with clay. It lays five or six eggs, of a pale bluish green, marked with dusky spots.

4. The *iliacus*, or redwing, has a very near resemblance to the thrush; but is less: their colours are much the same; only the sides under the wings and the inner coverts in this are of a reddish orange, in the thrush yellow; above each eye is a line of yellowish white, beginning at the bill and passing towards the hind part of the head.

These birds appear in Great Britain a few days before the fieldfare: they come in vast flocks, and from the same countries as the latter. With us they have only a disagreeable piping note; but in Sweden during the spring, they sing very finely, perching on the top of some tree among the forests of maples. They build their nests in hedges, and lay six bluish-green eggs spotted with black.

5. The *merula*, or black-bird, when it has attained its full age, is of a fine deep black, and the bill of a bright yellow; the edges of the eye-lids yellow. When young, the bill is dusky, and the plumage of a rusty black, so that they are not to be distinguished from the females; but at the age of one year they attain their proper colour.

This bird is of a very retired and solitary nature; frequents hedges and thickets, in which it builds earlier than any other bird: the nest is formed of moss, dead grass, fibres, &c. lined and plastered with clay, and that again covered with hay or small straw. It lays four or five eggs of a bluish-green colour, marked with irregular dusky spots. The note of the male is extremely fine, but too loud for any place except the woods: it begins to sing early in the spring, continues its music part of the summer, descends in the moulting season, but resumes it for some time in September and the first winter-months.

6. The *torquatus*, or ring-ouzel, is superior in size to the black-bird; the length is 11 inches, breadth 17. The bill in some is wholly black, in others the upper half is yellow; on each side the mouth are a few bristles; the head and whole upper part of the body are dusky, edged with pale brown; the quill-feathers and the tail are black. The coverts of the wings, the upper part of the breast, and the belly, are dusky, slightly edged with ash-colour. The middle of the breast is adorned with a white crescent, the horns of which point to the hind part of the neck. In some birds this is of a pure white, in others of a dirty hue. In the females and in young birds this mark is wanting, which gave occasion to some naturalists to form two species of them.

The ring-ouzel inhabits the Highland hills, the north of England, and the mountains of Wales. They are also found to breed in Dartmoor, in Devonshire, and in banks on the sides of streams. The places of their retreat is not known. In Scotland and Wales they breed in the hills, but descend to the lower parts to feed on the berries of the mountain-ash. They migrate in France at the latter season; and appear in small flocks about Monthard in Burgundy, in the beginning of October, but seldom stay above two or three weeks.

7. The *cinclus*, or water-ouzel. See *STURNUS*, species 2. where it was inserted by mistake as a species of that genus.

8. The *polyglottus*, or mocking-bird, is a native of America. It is about the size of a thrush, of a white and grey colour, and a reddish bill. It is possessed not only of its own natural notes, which are musical and solemn, but it can assume the tone of every other animal in the wood, from the wolf to the raven. It seems even to sport itself in leading them astray. It will at one time allure the lesser birds with the call of their males, and then terrify them when they have come near with the screams of the eagle. There is no bird in the forest but it can mimic; and there is none that it has not at times deceived by its call. But, unlike such as we usually see famed for mimicking with us, and who have no particular merit of their own, the mock-bird is ever sure to please when it is most itself. At those times it usually frequents the houses of the American planters; and sitting all night on the chimney-top, pours forth the sweetest and the most various notes of any bird whatever. It would seem, if accounts be true, that

Turkey.
Turgence
Turkey.

that the deficiency of most other song-birds in that country is made up by this bird alone. They often build their nests in the fruit-trees about houses, feed upon berries and other fruits, and are easily rendered domestic.

TURGESCE, among physicians, denotes a swelling, or growing bloated.

TURIN, an ancient, populous, strong, handsome, flourishing city of Italy, and capital of Piedmont, where the sovereign resides, with an archbishop's see, a strong citadel, and an university. It is seated on a vast plain, at the confluence of the rivers Doria and Po. It is one of the handsomest places in Italy; but the air is unhealthy in the autumn and winter, on account of the thick fogs. One half of this place is lately built; and the streets are straight and clean, being washed by an aqueduct. The two largest streets are the New-street, and that of the Po, which are lighted in the winter time. The houses are handsome, and all built of the same height. The ducal palace consists of two magnificent structures, joined together by a gallery, in which are several statues, all sorts of arms, the genealogy of the dukes of Savoy, a representation of the celestial signs, a royal library, and many other curiosities. Besides these two structures, there is the palace of the prince of Carignan, the hospital of St John, the seminary of the Jesuits, the royal hospital, and the metropolitan church of St John, wherein they pretend to keep the cloth in which is the print of the face of Jesus Christ. There are all superb structures. When the plague reigned at Marseilles in 1720, a great number of artificers withdrew to Turin; inso much that there are now above 54,600 inhabitants, and 48 churches and convents. Turin is very well fortified, and extremely strong; as the French found by experience in 1706, who then besieged it a long while to no purpose. The citadel, which is flanked with five bastions, is without doubt a masterpiece of architecture. There are very fine walks on the ramparts, which require two hours to pass round them. There are also very fine gardens on the side of the river Po; and the house commonly called *La Charité* is remarkable, as there is room for 3000 poor people. The college of the academy is very large and well-built, and has a great number of ancient inscriptions. In the royal library are 19,000 manuscripts, besides 30,000 printed books; when the last king died, a present of 7000 was made to the university. It is charmingly seated at the foot of a mountain, 62 miles north-east of Genoa, 72 south-west of Milan, and 280 north-west of Rome. E. Long. 7. 45. N. Lat. 44. 50.

TURKEY, in ornithology. See MELEAGRIS.

TURKEY, a very extensive empire, comprehending some of the richest countries in Europe, Asia, and Africa. See TURCÆ.

Under the article **CONSTANTINOPLE**, n^o 115, *et seq*, we have given an account of the origin and progress of the Turks, as far as seemed necessary for understanding the subsequent and more important part of their history. In 1453 they made themselves masters of the city of Constantinople, which from that time became the capital of their empire. Mohammed II. at that time the sultan, after having treated the inhabitants with the greatest cruelty, began to think of adding Servia to his dominions. Accordingly, in 1454, he entered that coun-

try at the head of 20,000 men, and obliged the inhabitants to pay him an annual tribute of 40,000 ducats. On his return to Adrianople, Mohammed re-peopled the towns and villages about Constantinople with 4000 men and women who fell to his share; and going to that city, built a palace eight stadia in compass, which he lined with lead taken from the monasteries. Next year a fleet was sent against the islands of Rhodes and Chios; but the attempt on both proved unsuccessful: however, the island Cos was reduced, and some other places; after which the sultan, turning his arms towards Hungary, laid siege to Belgrade. At first he met with success; beat down part of the wall, and stopped the navigation of the river with 60 vessels: but the celebrated John Hunniades, happening to arrive at that critical juncture, made a furious sally, entirely routed the Turkish army, wounded Mohammed himself in the thigh, and burnt all his ships. Hunniades himself did not long survive this engagement, dying soon after of a wound he had received therein, according to some, or of the plague, according to others.

Mohammed being thus repulsed from Belgrade, set about the entire conquest of the Morea, the ancient Peloponnesus. The Grecian princes, among whom were two of the emperor's brothers, Thomas and Demetrius, were so terrified by the taking of Constantinople, and the great progress of the Turks, that they prepared to retire into Italy; upon which the Albanians seized on the country, choosing one Manuel Cantacuzenus, a Greek, for their prince. Then falling on the Greeks who remained, they made an offer to the sultan of the cities and fortresses, provided he would allow them to keep the open country; for the Albanians were shepherds, who had no fixed habitation. At this time, however, the sultan chose rather to support the Greeks than let the country fall into the hands of such barbarians; and having defeated the Albanians, was content to accept of a tribute from the Greeks. But the danger was no sooner over, than the Grecian princes revolted anew; upon which Mohammed entering the country with a powerful army, prince Thomas, with his family, fled to Italy; while Demetrius thought it most eligible to submit to the sultan, by whom he was carried away, with many of the most considerable persons of Lacedæmon, Achaia, &c. where Turkish governors were appointed. Two thousand families were also carried away from the Morea, in order to be settled at Constantinople, and 2000 young men to be enrolled among the sultan's troops. Many cities at this time fell into the hands of the Turks, among which the principal were Corinth and Athens. The Greeks, however, still made some faint struggles; but all in vain: for by the year 1459 the whole country was subdued, excepting some maritime places held by the Venetians; and prince Thomas was obliged finally to take up his abode at Rome, where he was lodged in the pope's palace, and had a pension of 3000 livres a year allowed him for his expenses.

Mohammed now pursued his good fortune; and having made war on the emperor of Trebizond, he subdued his dominions, and put him to death. His career, however, was for some time stopped by Scanderbeg the Epirote. This prince had already defeated an army of 12,000 Turkish horse, of whom only 5000 escaped the slaughter; and dispersed another, against the

Turkey. with the loss of their general, and 4120 of his men killed on the spot. Encouraged by this success, he laid siege to Belgrade, which it seems was now in the hands of the Turks: but, through the treachery of his scouts, his army was defeated, and 5000 of his men killed; upon which, one of his generals, by name *Mofet*, went over to the Turks.

Scanderbeg, not at all dispirited by this misfortune, prosecuted the war with the utmost vigour. His first enterprise was against his perfidious general Moles, who had been immediately put at the head of an army by the sultan. This army was by Scanderbeg totally destroyed, excepting about 4000 men; upon which Moles fell into such disgrace with the Turks, that he returned to his old master, who forgave his treachery, and restored him to all his former posts.

The bad success of Moles did not prevent Amefia, the nephew of Scanderbeg, from following his example. Mohammed received him kindly, and lent him with Ishak bafhaw of Constantinople; whom he intrusted with an army of 50,000 men, against his uncle. Scanderbeg with only 6000 men, retired towards Lyfia, a maritime city of the Venetians. The Turks pursued, contrary to the advice of Amefia; and being surprised by Scanderbeg, were utterly defeated, with the loss of their camp, 20,000, or, according to others, 30,000 men killed on the spot, and the treacherous Amefia taken prisoner. With the like good fortune Scanderbeg defeated three other Turkish armies, one of 20,000, another of 30,000, and the third of 18,000 men. On this Mohammed sent against him an old experienced commander, at the head of 40,000 chosen troops; but as he likewise was able to achieve nothing, the sultan thought proper to conclude a peace with Scanderbeg, in 1461.

Mohammed being thus freed from such a troublesome enemy, completed the conquest of the Greek islands; subdued Walachia, Bosnia, and Illyria, extending his empire nearly to the confines of Italy. But as it was easy to see that no conquest would satisfy the Turkish ambition, the Venetians, who found themselves ill treated by their warlike neighbours, entered into an alliance with the Hungarians to repress the overgrown power of the Turks, and prevent the western parts of the world from being totally over-run by them; and into this alliance Scanderbeg was soon drawn, notwithstanding his treaty with Mohammed already mentioned. The Hungarians invaded the Turkish dominions on the west side, defeated some troops, and carried off 20,000 slaves: the Venetians invaded the Morea, where they made some conquests, but were soon obliged to abandon them: however, they recovered the island of Lemnos; but being defeated in two engagements at land, they were obliged to solicit assistance from France, Germany, and Spain. Having obtained considerable supplies from those parts, they again entered the Morea; but meeting with still worse success than before, they applied for assistance to Matthias, the son of John Hunniades king of Hungary. Matthias willingly made another incursion into the Turkish dominions, ravaged Servia, and carried off a vast number of prisoners with a great booty.

In the mean time Mohammed, fearing lest Scanderbeg should be declared generalissimo of the Christian forces, sent to him, desiring a renewal of the league be-

tween them. But this being refused, the war was renewed with the utmost vigour. Many Turkish armies were sent against this hero; but they were utterly defeated and dispersed, till the year 1466, when by his death the sultan was freed from the most formidable enemy he had ever encountered.

The death of Scanderbeg was followed by the entire reduction of Epirus and Albania. The Venetians Albania reduced. In 1469 defeated the Turks in a pitched battle; but were driven out of Negropont, at that time the strongest city in Europe: after which they entered into an alliance with Ferdinand king of Naples, Lewis king of Cyprus, and the grand master of Rhodes, at the same time that they sent ambassadors to Uzun Hassan king of Persia, in order to persuade him to attack the Turkish dominions on the east side. Mohammed did not lose his courage at the number of his enemies; but having defeated the Persians, reduced the Venetians to such distress, that they were obliged to conclude a treaty in 1479.

In 1481 the war was renewed, and the city of Rhodes besieged, but without success; however, the city of Cephalonia was taken from the Venetians, Italy invaded, and the city of Otranto taken. This was the last of the exploits of Mohammed II. who died this year of the gout, and was succeeded by his son Bajazet II. or Bajazet II. Under this prince a war commenced with the Mamelukes of Egypt, which, under his successor Selim I. ended in the total subjection of that country. Bajazet, however, greatly facilitated Selim's conquest by the reduction of Circassia, from whence the Mamelukes drew their principal resources. Caramania and Croatia were totally reduced; the cities of Lepanto, Modon, and Durazzo, taken by the Turks, though the Venetians recovered Cephalonia; Syria on the east, and Moldavia on the west, were invaded and ravaged by the victorious armies of the sultan; till at last a peace was concluded with the European powers in 1503.

The year 1509 is remarkable for a dreadful earthquake at Constantinople, which overturned a great number of houses, and destroyed 13,000 people; being also followed by an epidemic distemper, which carried off great numbers. About this time also the sultan, finding the infirmities of old age drawing on, and being desirous of passing the remainder of his days in quiet, resolved to resign the throne to his eldest son Ahmed. But having engaged in this affair with too favour of great precipitation, and before he had gained over his eldest grandees, his second son Selim, whom he had made governor of Trabezond, hastily crossing the Euxine sea, dethroned and put to death his father, in the year 1512.

The new emperor, who had not scrupled to sacrifice his father to his ambition, did not hesitate at establishing himself on the throne by the death of his brother also. Accordingly, as Ahmed, knowing he could be no where safe, resolved to stand on his defence, Selim with a powerful army marched against him; and having defeated the few forces of his brother, took him prisoner, and put him to death. Having thus secured himself, he marched against the Persians, whom he overthrew in a great battle: after which he took the city of Tauris; made some other conquests; and having secured tranquillity on the eastern side of his dominions, turned

Turkey. turned his arms against Sultan Gauri of Egypt. Him he reduced in the manner related under the article EGYPT, n° 100. His farther designs of conquest were frustrated by his death, which happened in the year 1519.

24 Is succeeded by Solymán a warlike prince. Selim was succeeded by his son Solymán I. surnamed *Kanuni*, or *The lawgiver*, who proved no less ambitious and warlike than his father. Having defeated and killed the governor of Damascus, who had rebelled against him, he attacked the European princes with a design to extend his dominions as far to the westward as he possessed to the eastward of his capital. In 1520, he set out with a great army to conquer Hungary. The city of Belgrade was immediately invested, and in a short time taken. Rhodes also being attacked by a great force by sea and land, was obliged to submit, after a most desperate resistance, as is related under that article, n° 31 *et seq.*; and Solymán entered the city in triumph on Christmas day 1522. His conquests for some time were stopped by a rebellion in Egypt; but this being soon quashed, the war with Hungary was renewed in 1525. King Lewis having rashly engaged the Turkish army of 200,000 men with only 25,000, was utterly defeated, himself drowned in a ditch, and his whole army, excepting a few horse, cut in pieces. This defeat was followed by the surrender of Buda, which, however, the Hungarians retook in 1528; but next year it was again taken by the Turks, and soon after, both the Moldavians submitted to their jurisdiction.

25 The city of Rhodes reduced. The city of Vienna besieged without success. The city of Vienna was then invested; but after being reduced to the greatest straits, the sultan was obliged to abandon the siege by the coming on of the autumnal rains; which, however, he did not without barbarously massacring all his prisoners.

26 The king of Hungary defeated and killed. The raising the siege of Vienna was followed by an entire repulse of the Turks from the German territories on which Solymán, resolving to extend his dominions on the east, subdued the country of Georgia, and made himself master of the city of Bagdad; at the same time that his admiral, the celebrated Barbarossa, ravaged the coasts of Italy, and took the cities of Biserfa and Tunis in Africa. But, in 1536, he was obliged to retire before Charles V. of Spain, who retook the city of Tunis. Solymán, to revenge this disgrace, suspended for a time the war in Persia, in order to turn all his forces against Italy: but while this country was in danger of being totally overwhelmed, a Venetian captain having rashly taken and sunk some Turkish vessels, Solymán changed his design of attacking Italy into that of chastising the Venetians. However, after some trifling encounters, a peace was concluded in 1540.

27 Georgia, Bagdad, &c. reduced. This year the war was renewed in Hungary: the transactions were very unfortunate for the Christians, and ended in the entire reduction of the kingdom to a Turkish province. The kingdom of France, being oppressed by its enemies, entered into an alliance with Solymán, who was now grown so powerful, that the whole European power seemed scarce able to resist him. However, in 1565, he was baffled by the knights of MALTA, as is related under that article; and in 1566 an end was put to his ambition and his conquests by death.

28 Hungary reduced to a Turkish province. Solymán was succeeded by his son Selim II. surnamed *Mesir*, or *The Drunken*. Under him the empire

at first lost nothing of its lustre. But in 1571 the maritime power of the Turks was almost entirely destroyed at Lepanto, where one of the most remarkable sea engagements mentioned in history took place. The Christian fleet was commanded by Doria the Venetian admiral; and consisted of 78 Spanish and 3 Maltese galleys, under Don John of Austria, natural son to the emperor Charles V. Besides these, under Venieri a Venetian officer, were 108 galleys, 6 galleasses, 2 tall ships, and a great many small galliots. Colonna, a kinsman of the pope, had also 12 of his galleys under his command. On board this fleet were 20,000 good soldiers, many of them persons of great quality, who went volunteers in the expedition. The Turkish fleet consisted of 335 sail; but the most experienced officers were against fighting at that time, considering the great strength of the confederates, and that there was no necessity for an engagement. But the opinion of Ali Pasha the chief admiral, who was for a battle, prevailing, Parteu Pasha, the next in command, took on board 12,000 janissaries and spahis, drawn out of the neighbouring garrisons; besides 4000 other soldiers. Then putting out of the gulf, the fleet steered their course for the idle of Corzulates, of old Echinates, half-way between Lepanto and Patras. Their line of battle was thus: Parteu and Ali Pasha commanded the centre, Mohammed Beg with 56 galleys was in the right wing, and Kilij Ali with 95 galleys in the left; while Morad Dragut, with 30 galleys, and several other small vessels, brought up the rear. Mean time, the Christians moving towards them, both fleets came in sight, October 7. afternoon. Hereupon Don John, having ordered the great ensigns of the confederates, which was the signal for engaging, to be hoisted, clad in armour, went in his long boat to encourage the several squadrons of the centre under his command; while Doria did the like in the right wing, and Barbadioc, the Venetian proveditor-general, in the left.

The day was now well spent, when both fleets were ready for the battle, which was one of the most considerable that ever happened at sea. The signal was no sooner given, than the Turks, with a hideous cry, fell on six galleasses which lay at anchor near a mile ahead of the confederate fleet; but those ships fired so briskly on them, first from their forecables, and then as they passed by, so galled their galleys with whole broadsides, that several of them were sunk, which made the rest bear farther off. The wind likewise chopped about to the west, and incommoded the Turks with the smoke. However, they soon made good their disordered squadrons, and came on with surprising resolution. Ali Pasha observing the admiral's galley, ran upon her with such violence, that both their beaks were broken off, and fell into the sea. Hereupon ensued a most terrible fight between these two great commanders, and the other ships which seconded them; but as there were in Don John's galley 400 men picked out of the whole army, and consisting mostly of officers, they entered the enemy's galleys three times to the very main-mast, yet were as often repulsed.

Venieri, seeing how things went, hastened to the general's relief; but on his way was encountered by Parteu Pasha with his galleys. Here the Turks behaved so bravely, that notwithstanding the example and amazing courage of that admiral, now 70 years old, they

Turkey. Account of the battle of Lepanto.

they entered the prow of his galley, and must have taken it, had not the sudden coming of two brave Venetian captains to his relief turned the scale a little, though with the loss of their own lives. At length Venier's ship took two of the Turkish galleys, while Parteu Pasha fled out of the danger in a long boat. Not far from thence Colonna, the pope's admiral, being furiously engaged, made great slaughter of the enemy, and took one galley. Ligni the Genoese admiral did the like; on board of whom the prince of Parma, with other volunteers, gained immortal honour.

At the same time, Mohammed Beg falling on the galleasses with the right wing, and being sorely damaged by them, to avoid this inconvenience, as also a shelfe lying between him and the shore, he sent Ali, a Genoese renegade, with great part of his galleys, round about on the right, to fall on the rear of Barbado, who presently tacked about to receive him. But as he had no fewer than five galleys at a time upon his own, he in this terrible fight grappling with the enemy, and shunning no danger, was struck in at the left eye, and almost through the brain, with an arrow; of which wound he died three days after. This encouraged the Turks so much, that the galley must needs have been lost, had not the been speedily relieved by Nani and Portia. These presently cleared her of her boarders, among whom they made a great slaughter: but were themselves dangerously wounded; and had been lost if more galleys had not come to their assistance; with which reinforcement they took one of the principal galleys of the enemy. Not far from thence, the noble Giovanni Contareni had a terrible engagement with Mohammed Beg; whose galley at length being taken, and all the men either slain or forced overboard, he was found half dead, and dispatched out of the way.

Don John, who had been three hours engaged with Ali Pasha, finding himself in much danger notwithstanding the assistance from Bacianono in the rear, on a sudden called forth his 400 select men from under the hatches, by whose valour that admiral's galley was soon taken. The Pasha himself being mortally wounded, and all over bloody, was slain outright; and his head being cut off, was held aloft on the point of a spear by Don John as a trophy of his victory. This fight, with the cry of victory through the Christian fleet, so discouraged the rest of the galleys which were still valiantly fighting, that they fled towards the shore, about a mile distant: but several of them were taken by Canalis, who commanded the galleys of Candia. Among the slain was Karakojia, the famous renegade pirate; while Ahmed and Mohammed, the two sons of Ali Pasha, and nephews of sultan Selim, were both taken aboard their galley.

For all this good success, the fortune of the day was still doubtful in the right wing, where Doria was engaged with Kilij Ali, a valiant and expert commander. The Spanish admiral at first seemed to keep off, while the Turkish extended his wing as if to hem him in; yet offered not battle, expecting some advantage. This he soon obtained by enclosing 12 of the Venetian galleys separated from the rest, which he boarded and took; only Superantio, a nobleman, rather than fall into the enemy's hand, blew himself and his galley up. Mean time the noise of the firing in

this part of the fleet brought Pietro Justiniani, admiral of Malta, to Doria's assistance; but coming up singly, he was presently attacked by six Turkish galleys, which plied him so close, that he was on the very brink of being lost. But two of the other Maltese galleys, which were engaged with three of the enemy's, seeing the danger their admiral was in, came presently and rescued him. Kilij Ali, by this time understanding that the centre and right wing of the fleet was overthrown, thought it best to make his escape; which with some difficulty he effected, with 25 galleys and 10 galliots, into the gulf of Lepanto.

The number of Turks slain in this famous naval fight could not with certainty be known. An author, who wrote an account of this war, makes their number 32,000 besides prisoners, who were about 3500. The galleys taken from them amounted to 161. Forty more were sunk or burnt; and of galliots, with other small vessels, about 60 were taken. The Turkish admiral's galley was exceedingly rich and beautiful. In it was found Ali Pasha's casket, with 6000 ducats in it. This, with a yearly pension of 300 ducats, was given in reward to a Greek of Macedonia, who slew that admiral. He was likewise knighted for that exploit by Don John; and had the barrel of the Turkish standard bestowed on him. This barrel, on his return to Venice, he sold to a goldsmith; and the senate bought it of the goldsmith, paying a ducat for every ounce, to deposit it among the other trophies of that victory.

Notwithstanding the prodigious loss sustained by the Turks on this occasion, the confederates reaped but little advantage from this victory; and next year Kilij Ali Pasha, who had succeeded to the post of high admiral, fitted out a fleet of 250 galleys, which he ravaged the coasts of Christendom wherever he came, and maintained his ground so well, that the confederates could never gain the least advantage over him.

The Turkish power from this time, however, began to decline. The progress of civilization being much more quick among the western nations, and their improvements in the art of war very considerable, the Turks found it not only impossible to extend their dominion over Germany, but even found it a matter of some difficulty to withstand the power of the western princes. During the remainder of the reign of Selim, the war was carried on in Hungary with little advantage on either side; but under his successor, sultan Morad III. the Turks met with several severe checks from the Germans.

In 1594, Mohammed III. having succeeded his father Morad, destroyed his 19 brethren, in order to secure himself on the throne; and for the same reason caused ten of his father's wives and concubines to be thrown into the sea, lest any of them should prove with child. The emperor Rodolph II. having entered into a confederacy against him with the princes of Transylvania, Wallachia, and Moldavia, defeated the Turks and their Tartar auxiliaries in several engagements, and took many cities; while so grievous a famine and plague raged in Hungary, that of 85,000 Tartars who had entered the country the year before, scarcely 8,000 remained alive. This was followed by new misfortunes; so that in the year following the

Turkey.

Turks were entirely driven out of Transylvania, Moldavia, and Walachia; notwithstanding which the war continued for some time, though generally to the disadvantage of the Turks.

38
War with Poland.

In 1621, under Othman, or Ozman, II. we find the Turks first engaged in a war with Poland. In this, however, the sultan found himself unable to succeed, though he opposed an army of 30,000 strong to 40,000 Poles and 8000 Germans. A peace was therefore concluded the same year; the chief article of which was, that the Poles should have a free trade in the Turkish dominions, and that for this their merchants should pay 10,000 sequins. The Turkish affairs continued pretty much in the same way till the year 1673, when a dreadful war broke out with Germany, Russia, and Poland, whose army was at that time commanded by the celebrated John Sobieski.

40
War with Russia, Germany, and Poland.

The year before, hostilities had commenced on account of the Poles having endeavoured to detach the Cossacks from their allegiance to the sultan. At this time the Turks were successful, through the dissensions which reigned among the Poles; and the latter were obliged to pay an annual tribute of 20,000 rixdollars, and to deliver up 48 towns and villages in the territory of Kamienieck. However, the articles of this treaty were never executed; for, in 1673, the states of Poland sent a letter to Kyopriili Ahmed Pasha the vizir at that time, informing him, that they considered as null the conditions of the treaty, being concluded without their consent, and that they would rather suffer death than submit to the infamy of paying one single farthing by way of tribute. On this the sultan, Mohammed IV. determined to take a severe revenge on their perfidy, set out with a great army; but was entirely defeated, with the loss of 20,000 men killed on the spot, all the baggage, 25,000 waggon-loads of provision and ammunition, and 2000 purses of money for paying the army. Soon after this victory, John was proclaimed king of Poland: but his subjects, jealous of his glory, refused to support him properly in prosecuting his advantage; so that, four years after, a treaty was concluded, by which the Poles for ever resigned their pretensions to Kamienieck and to the dominion of the Cossacks in Podolia.

43
The Turks defeated, and peace concluded.

But though peace was thus made with Poland, the war was carried on very unsuccessfully with Russia. In 1678, an army of the Tartars was entirely cut in pieces or taken near the city of Cherin; which so intimidated another army of 40,000 Turks, who had waited for the arrival of these auxiliaries, that they threw away their arms, and fled without stopping till they had crossed the river Bog. This defeat inclined the sultan to peace; but the negotiations proving ineffectual, he, in 1679, again sent a powerful army of 80,000 Turks, 30,000 Tartars, and 4000 Cossacks, under the command of the wazir, to retrieve his lost honour. This army, however, succeeded little better than the former: for the wazir was defeated in several engagements; and at last, according to custom, put to death on account of the bad success of the war. In 1684 the Venetians again declared war, while the Poles and Germans continued their hostilities with the utmost violence. The Turks were forced to yield to the superior fortune and valour of their adversaries; they were defeated in a great number of engagements, and lost many

places of importance. In short, their affairs seemed to be totally going to wreck, when, in 1688, they were retrieved by the new wazir Ahmed Kyopriili, a man of great skill and experience in war, as well as of the most upright and blameless character. Having prevailed in the divan to have the war carried on, he applied his whole care to the raising of an army and providing warlike stores. But finding the people everywhere intimidated and unwilling to oppose the enemy, the treasury exhausted, and an universal languor prevailing, he made a new kind of proclamation, in which he told the people, that "as he found it necessary to trust the command of the army against the haughty Germans to none but himself, so he would not employ in this expedition any soldiers forced into the service; as knowing that the will was of more value with God than the deed: that he would only put the Mussulmans in mind, that, by the precepts of God and his prophet, every one is commanded neither to avoid martyrdom, nor to despair of success against Infidels," &c. Having thus once roused the enthusiasm of the common people, they flocked in great numbers to his standard; after which, having reformed many abuses both in the civil and military departments, he led them against the enemy. The good effects of his reformations were evident. Great numbers of the enemy were cut off, and almost all the important places taken which had been lost before, when, in 1691, he was defeated and killed by the Germans at Islanakmen.

After his death, the Turkish affairs again fell into disorder, and, though the utmost efforts were used by succeeding vizirs, no progress could be made; and, in 1697, a prodigious overthrow was given them by prince Eugene at Zenta. At last, in 1698, all parties being weary of such an expensive and ruinous war, a pacification took place at Carlowitz, but on different terms, with the different nations who had been at war with the Turks. The emperor made a truce for 25 years, upon condition that all Transylvania should be resigned to him: the city of Temeswar was to be restored to the Turks, and the navigation of the Teisse and Maros rivers be free to both nations; that the country between the Danube and the Teisse, called *Bachbak*, remain in the emperor's hands; that the boundary of the eastern part of Hungary, belonging to the emperor, should be a right line drawn from the mouth of the Maros towards the banks of the Teisse to the mouth of the Bosut, where it falls into the Save; that towards the south the Save should part the Turkish from the imperial limits, till it receives the Uma; and that no new castles besides Belgrade and Peterwaradin should be erected, or old ones fortified, any where within those boundaries.

The Russian ambassador made a truce only for two years, upon the foot of each party possessing what he had taken. The Poles made a truce on the like terms with the sultan; namely, that they should have Kamienieck, Podolia, and Ukraina restored to them, in the same extent as possessed by them before sultan Mohammed's first expedition into Poland; and, on the other hand, resign Soczava, Nemoz, and Soraka, in Moldavia, to the Turks. The Venetians obtained these conditions: That all the Morea, as far as Hexamilos, should belong to them; and the firm land, with Naupaktum (or Lepanto), Prevesa, and the castle of Romania,

Turkey.

47
The Turkish affairs retrieved by Kyopriili.

49
He rouses the enthusiasm of the people.

49
Is at last defeated and killed.

50
Peace concluded.

51
Terms made with the emperor.

52
With the Russians.

53
With the Venetians.

Turkey. Romania, which had been demolished, should be restored to the Turks; that the bay of Corinth should be common to both, and the Venetians possess Lencade with the adjacent islands. The yearly tribute paid by the islands in the Archipelago to the Venetians was to be abolished; and Zakynth to be declared free from the like burden by the Turks. In Dalmatia, Knin, Cing, Kikht, Verlika, Duare, and Vergoraz, were to be left to the republic, and fixed as the boundaries of their dominions on that side. The Ragusians were to continue free, and the Venetians to retain the castles of Castelluovo and Rifano, with what they possessed in the neighbourhood. Both parties were allowed to fortify their borders with new fortresses; or to repair those which were decayed, excepting Naupaktum, Preveza, and the castle of Romania before mentioned.

54 From the conclusion of the peace of Carlowitz to the year 1769, nothing very remarkable occurs in the Turkish history, excepting their recovery of the Morea from the Venetians by the treaty of Passarowitz. See the article VENICE. Their war with the Russians under Peter the Great has been taken notice of under the article RUSSIA; those afterwards with PERSIA, under that article. None of these, indeed, were of any great consequence; but, in 1769, a war commenced with Russia, which threatened the Ottoman empire with destruction, and which has given it such a severe check as it can scarcely recover. The origin of this war is given under the article POLAND, n^o 94; and during the course of it, an almost uninterrupted train of successes attended the Russian arms.—About the end of March 1769, a body of Russian troops made themselves masters of the important fortress of Alopeh, at the mouth of the river Don. In the end of April, prince Gallitzin, commander in chief of the Russian army on the frontiers of Poland, passed the river Niester, hoping to take the fortress of Choczim by surprise; but being disappointed, he was obliged to return. Near the beginning of July, however, he again passed that river, and on the 13th attacked and defeated the van of the grand vizir's army, consisting of about 50,000 or 60,000 men. Thirteen thousand of the fugitives entered Choczim; which was next day invested by the Russians: but they were at last obliged to raise the siege, and repass the Niester; which they could not effect without considerable loss.

58 In the mean time both the Ottoman and Russian courts were displeased with the conduct of their generals. The Turkish grand vizir was deprived of his command, and afterwards beheaded; and was succeeded by Moldovani Aga Pacha, a man of a bold and enterprising spirit. On his first taking the command of the army, finding it impossible to subsist where he was, he attempted to force a passage over the Niester; but being three times repulsed with great loss, he made a precipitate retreat towards Bender, at the same time drawing the troops out of Choczim, which the Russians immediately took possession of.

59 Prince Gallitzin was now superseded by general Romanzow, who took the command of the army on the 29th of September. Soon after his arrival, he received news of the success of general Elmt, who, with a body of 10,000 men, had reduced the province of Yassy. He invested Bender; but finding the season

of the year too far advanced, he soon withdrew his troops, and put them into winter-quarters.

This first campaign had proved so unpropitious to the Turkish affairs, that the court would gladly have concluded a peace, if they could have obtained it upon honourable terms; but the Russians insisting upon the entire cession of Moldavia and Walachia as a preliminary article, the negotiations came to nothing. A new campaign was therefore resolved on; and this proved still more unsuccessful than before. The grand Russian army under general Romanzow passed the Niester in the month of May 1770; and, having assembled at Choczim on the 3d of June, marched towards Pruth: at the same time their second army, commanded by general Panin, arrived before Bender. The plan of operation was, that the latter should form the siege of Bender, and Romanzow should cover it.

61 On the 18th of July, general Romanzow attacked an army of 80,000 Turks and Tartars, commanded by the Khan of Crimea, and strongly entrenched on an almost inaccessible mountain, forced their intrenchments, and obliged them to flee in the utmost confusion, leaving an immense quantity of ammunition and provisions, &c. in their camp; which they totally abandoned to the victors.—After this victory, the Russian general pushed on towards the Danube; and on the 2d of August attacked another Turkish army, commanded by the grand vizir in person, and totally defeated it, making himself master of their camp, ammunition, 143 pieces of cannon, and above 7000 carriages loaded with provisions. The loss of the Turks on this occasion was not reckoned less than 40,000 men, and some accounts raised it to 60,000.—During the course of this summer also, the fortress of Kilis Nova, at the most northerly mouth of the Danube, surrendered by capitulation; and likewise that of Ackerman, or Bialogorod, near the mouth of the Niester. Bender was taken by storm on the 27th of November; and the Russians, enraged at the obstinate resistance they had met with, made a terrible slaughter of their enemies. It was computed that 30,000 Turks perished on this occasion. The fortress of Brailow, situated on the northern side of the Danube, was invested on the 26th of September; and the garrison were so much intimidated by the taking of Bender, that they abandoned the place, and most of them were drowned in crossing the river.—During this campaign, it was reckoned that the Russians took 1000 pieces of cannon from their enemies.

65 This year also a Russian fleet of 16 or 18 ships entered the Mediterranean, and landed a body of troops fleet lands on the Morea. These being joined by the Greeks, some troops committed great cruelties on the Turks, and made on themselves masters of almost the whole country. At last, however, the Porte, notwithstanding their bad success in other parts, found means to send a force into the Morea sufficient to overpower the Russians. The Greeks now suffered in their turn; and the Russians, hearing that a Turkish fleet had passed the Dardanelles, abandoned the Morea, and failed to meet their antagonists. A battle ensued, in which the Turks were defeated; and having imprudently retired into a neighbouring harbour, they were next day entirely destroyed by the Russian fire-ships, except one ship of 64 guns, which was taken. This fleet consisted of

Turkey. Unsuccessful negotiations for peace.

63 Bender invested.

63 The Turks and Tartars defeated by General Romanzow.

64 The grand vizir defeated with prodigious slaughter.

65 Bender taken, and the inhabitants massacred.

66 Vast number of cannon taken by the Russians.

67 A Russian fleet lands on the Morea.

68 They destroyed the Turkish fleet.

Turkey. 15 ships of the line, from 96 to 60 guns, three large frigates, and seven large armed vessels, besides galleys. After this victory, the Russian fleet blocked up the mouth of the Dardanelles, interrupted the Turkish trade, prevented the carrying of provisions to Constantinople by sea, and raised contributions from most of the islands in the Archipelago.

69 They take Giurgewo and defeat general Essen.

70 In 1771, matters did not at first go on so successfully on the part of the Russians. On the side of the Danube, they were obliged to keep on the defensive. Another army, under prince Dolgorucki, had better success; they reduced the whole peninsula of Crim Tartary in less than a month, though defended by an army of 50,000 men.—During those transactions the Turks made themselves masters of the fortresses of Giurgewo; which enabled them to become so formidable on the side of Walachia, that prince Repnin durst not attack them. Upon his refusal to do so, he was deprived of his command; which was given to General Essen. On the 17th of August, he attacked the Turkish intrenchments; but, after a desperate engagement of four hours, was defeated, with the loss of upwards of 3000 men.

71 Are outwitted by General Romanzow.

72 Two Turkish armies totally defeated.

73 The grand vizir defeated, and driven beyond a vast quantity of artillery taken, and likewise the town and castle of Babadagh; while the vizir, with the remains of his army, fled 30 miles to seek refuge at Mount Hemus. A few days afterwards general Essen

74 The Turks driven out of Walachia, &c.

75 They sue for peace.

Turkey. that the Russians should enjoy an unlimited freedom of navigation on the Black sea, together with the possession of the city of Asoph, on the mouth of the Don; and that a sum of money should be paid them by way of indemnification for the expenses of the war. These terms, however, were rejected; and the negotiations, which continued through the whole year 1772, at last came to nothing. The commissioners on both sides retired from Bucharek, the place where the congress was held, on the 22d of March 1773. For some time a desultory kind of war was carried on between detachments from the two armies. But as this was very prejudicial to the Russians, who could not be so easily recruited as the Turks, about the middle of June, Romanzow made preparations for passing the Danube with the grand Russian army, consisting of 87,000 men: which, however, he did not accomplish till the 24th; and then marched with his army, in large divisions, towards the city of Silistria. He was terribly harassed on his march by large bodies of the Turkish cavalry, of whom the grand vizir had detached 27,000 for this purpose. At last, however, they arrived before the city, which was strongly fortified, and defended by a body of troops consisting of about 24,000 men. On the 29th of June, this body was defeated by General Weismann, who commanded the van of the Russian army, and forced to retire into Silistria. The grand vizir then detached 50,000 men to the relief of the place: upon this the Russians found it necessary to retreat; which was not accomplished without very great difficulty and loss. In this retreat General Weismann was killed, and the army left all their magazines behind them.

peace.

not fail to take advantage of these misfortunes. He placed the different divisions of his army in such advantageous situations, that he totally cut off all communication between the Turkish camp and every mean of subsistence. The unfortunate vizir, therefore, was obliged at last to submit to the terms which Romanzow dictated to him. The principal articles were, the independency of the Crimea; the absolute cession of Kilburn, Kerche, and Jenickala, and all the country between the Bog and the Dniپر; a free navigation in all the Turkish seas, in which was included the passage through the Dardanelles, with all the privileges and immunities which were granted to the most favoured nations. Russia gave up all her conquests, except Afoph and Taganrok. There were, besides, several stipulations in favour of the inhabitants of Moldavia and Walachia, and the Greek islands which were restored by Russia.

83
Account of
the Turkish
dominions.

The Turkish empire comprehends several countries in Europe, Asia, and Africa. In Europe it is bounded on the south by the Mediterranean; on the north, by Croatia, Sclavonia, and Transylvania; on the east, by Poland, Russia, and Asia; and on the west, by the Adriatic and Dalmatia. The principal countries of Turkey in Europe are Romania, Bulgaria, Servia, Walachia, Moldavia, Bessarabia, Greece, Macedonia, Albania, Thessaly, Levadia, Morea, and the Archipelago islands. Turkey in Asia is divided into Eastern and Western. The Eastern comprehends Georgia, Turcomania, and Dearbekr; and the Western, Anatolia, or Asia Minor, Syria, and Palestine.—In Africa the Turkish dominions are Egypt, and some districts of Barbary. But for an account of these different countries, see the articles as they occur in the order of the alphabet.

84
Of the go-
vernment,
&c. in Tur-
key.

The grand signior, or emperor of the Turks, is restrained by no laws or compacts, the government being purely monarchical: but if he indulges not the humours of the people, and especially of the mutinous janisaries, he is in danger not only of being deposed, but also of being put to death. Those who have offices under the government he squeezes, disgraces, and puts to death, upon the least suggestion of their dissaffection or misconduct, without giving them an opportunity of answering for themselves, they being looked upon as more immediately his slaves: but others seem to enjoy almost as great a degree of security, both in their persons and properties, as the subjects of other absolute monarchies. Indeed, in all such there is a gradation of governors and officers, of which the higher fleece and oppresses those below them, and the lowest make reprisals upon the common people. In the succession to the empire, no regard is paid to age or birth-right, the Turks thinking it sufficient if, in their elections, they keep to the family. Women are excluded from the throne. The emperor's council is either ordinary or extraordinary. The first, meeting every Sunday and Thursday, consists of the great officers of state, and is called the *galibé divani*. To the other, which is called *ajaké divani*, are summoned all the great persons and officers of the empire, and even the oldest and most experienced soldiers. The sultan hears what passes from an adjoining chamber. At the head of the ministry is the grand vizir, who is as it were his lieutenant-general, with whom he divides,

or rather to whom he leaves the care of the whole empire; he being entrusted not only with the finances, with foreign affairs, and the administration of justice in civil and criminal matters, but also with the conduct of the war, and the command of the army. Great and dangerous as this charge is, there have been men who have executed it with safety and success, both in peace and war, and have died quietly in their beds; but that is not the case with the most of them, it being the usual policy of the emperors to shelter themselves from the clamours of the people by throwing the whole blame of any mal-administration upon him, and giving him up to the public repentment. His income, without any breach of probity, may amount to 600,000 dollars, exclusive of presents and other perquisites. Notwithstanding his high dignity, his palace is open to every one, and he gives audience to the meanest of the poor. When the sultan names a grand vizir, he put into his hand the seal of the empire; and when he honours him with the command of an army, he takes out one of the plumes of his own turban at the head of the troops, and delivers it to him to place it in his own. The other great officers of state are the kaimakan, or vizir's deputy, not to be confounded with the governor of Constantinople, who is also called *kaimakan*; the vizirs of the bench, or bassas of three horse-tails, because three horse-tails are carried before them when they march, and who sit in the divan or courts of justice with him; the kadis, or chief justices of provinces; the beighlerbegs, or viceroys, of which the chief are those of Romelia, Natolia, and Damascus; the ordinary bassas, or governors of towns and districts under the beighlerbegs; the reis effendi, or lord chancellor and secretary of state; the tefterdar, or high treasurer; the aga of the janisaries; the aga of the spahis; the aga of the siluds, &c. The chief officers of the seraglio are the kishlaragi, who is superintendent of the women, and has the command of all the black eunuchs; the capî aga, who has the command of all the white eunuchs, and to whom all petitions to be presented to the prince are delivered. Both these are also eunuchs, and of the same complexion as those of whom they have the command. Besides the women and eunuchs, there are in the seraglio the ichoglans and azamoglans, mutes, dwarfs, and buffoons. The ichoglans are young men bred up in the seraglio, not only to serve about the prince, but to fill in time the first posts of the empire. The azamoglans are trained up there for inferior employments.

No children are admitted into the seraglios of Constantinople, Pera, or Adrianople, till they are first reviewed and approved of by the grand signior. They are generally the most beautiful, well-made, and sprightly, that can be met with. They are first taught, after being circumcised, silence and a modest humble behaviour. Then they are instructed in the Mohammedan religion, to speak and write the Turkish language, and afterwards the Persian and Arabic. As they grow up, they are taught manly exercises, and whatever is thought requisite to qualify them for state-employments: but they are seldom preferred out of the seraglio until the age of 40.

The ladies of the harem are a collection of young beautiful virgins, either the presents of governors, pure-

Turkey.

purchased, or captives taken in war; most of them being the children of Christian parents. They are taught music, dancing, and other accomplishments, and furnished with the richest cloaths and ornaments. Some of them frequently play and dance before the grand signior, while others divert him with their conversation. They have a great many female slaves to wait on them; but are scarce ever suffered to go abroad, except when the grand signior changes his place of residence; when a troop of black eunuchs convey them to the boats, which are enclosed with lattices: and when they go by land, they are put into close chariots, and signals made at certain distances, to give notice that none may approach the road through which they are to pass.

85
Dress,
manners,
&c. of the
Turks.

The Turks are generally robust and well-shaped, of a good mien, and patient of hardships, which render them fit for war. They shave their heads; but wear their beards long, except the military and those in the seraglio, who wear only whiskers. They cover their heads with a white linen turban of an enormous size, and never pull it off but when they sleep. None but Turks must presume to wear a white turban. Their breeches or drawers are of a piece with their stockings; and they have slippers instead of shoes, which they pull off when they enter a temple or house. They wear shirts, with wide sleeves, not gathered at the wrists, and over them a vest tied with a sash; their upper garment being a loose gown, something shorter than the vest.

The womens dress pretty much resembles that of the men; only they have a stiffened cap with horns, something like a mitre, on their heads instead of a turban, and wear their hair flowing down. When they go abroad, they are so wrapped up, that their faces cannot be seen.

The Turks sit, eat, and sleep, according to the custom of the east, on iophas or cushions, mattresses, and carpets. Rice is their most general food, and coffee their common drink. Their most usual salutation is to bow the head a little, laying the right-hand on their breasts; but to persons of rank they stoop so low as to touch the border of their vest. The women are kept under a rigorous confinement. They have generally delicate skins, regular features, black hair and eyes, with an admirable chest. Many of them are complete beauties. Their cleanliness is extraordinary; for they bathe twice a-week, and suffer not the smallest hair, or the least soil, to be upon their bodies. As to the qualities of their minds, they are said to want neither wit, vivacity, nor tenderness; and to be exceedingly amorous. It is no doubt for this reason that the men never suffer their wives faces to be seen, not even by the dearest friend they have in the world.

There is no need of much wit to behave one's self well here; for a good mien and gravity supply the place of merit in the east, and much gaiety would spoil all. Not that the Turks want wit; but they speak little, and pride themselves in sincerity and modesty more than eloquence. The Turks use no unnecessary words, whereas the Greeks talk incessantly. Though these two nations are born under one climate, their tempers are more different than if they lived in the most distant countries. The Turks make pro-

Turkey.

fession of candour and faithfulness, and are a charitable good-natured people, jealousy excepted, and very sober. On the other hand, they are extremely proud, insolent, indolent, superstitious, and covetous. They are also much addicted to unnatural lusts; and despise all other nations in general, especially those which are not of their religion. The common appellation that they give the Christians is that of dogs. An uniformity runs through all the actions of the Turks, and they never change their manner of living. They seem to have no kind of genius for the improvement of the arts and sciences, though they live under the influence of the same heaven, and possess the same countries, as the ancient Grecians d.d. They generally loiter away their time, either among the women in the haram, or in smoking or taking opium; and though they herd together, you will observe as little conversation among them as amongst so many horses in a stable. They seldom travel, or use any exercise or rural sports; and discover little or no curiosity to be informed of the state of their own or any other country: but Turkey, after all, is not without men of parts, probity, and honour; nor without benevolent, liberal, conversible, and ingenious people. They behave very commendably to their slaves and servants, and frequently better than the Christians do to theirs. There are no hereditary governments or titles of nobility in Turkey; and indeed the commonalty there enjoys the greatest liberty.

The languages spoken in Turkey in Europe are the Turkish and Tartarian, which have a great affinity and learn-
86
Languages to one another; the modern Greek, which differs widely from the ancient; the Slavonian, and Walachian. The Arabic is the language of the learned. Learning is at a very low ebb among the Turks: however, they have some schools, colleges, and academics; but they are on a very different footing from those among us. Not many years since, a printing-house was set up at Constantinople, where books of all kinds were allowed to be printed, except on matters of religion. The most ingenious musklemen employ themselves in reading the Alcoran and the commentators upon it, to which almost all their learning is confined. Some of them amuse themselves with poetry, in which they are said to succeed very well. Other Turks delight in music, and spend the whole day in playing upon an instrument, without being tired, though they only repeat the same tune. It is said there are a great many manuscripts in the Turkish, Arabian, and Persian languages, among the Turks; but it is not to be supposed that they contain any very deep, solid, ingenious, or useful learning.

The Turkish regular troops are the spahis and Forces.
87
timar-spahis, who are light-horse. The latter, who have estates in land assigned them instead of pay, are obliged to bring a certain number of slaves into the field with them. The tributary princes of Moldavia and Walachia, and the Crim Tartars, are also obliged to send auxiliaries. But the flower of the Turkish army consists of the janisaries, who amount to about 40,000, and are all infantry. They have particular privileges, being subject to no jurisdiction but that of their aga or commander. Their pay is three aspers a-day, besides victuals, and a suit of cloaths every year. They are all lodged at Constantinople together
in

Turkey.

in a fort of barracks, having been educated in the seraglio, and trained up to the exercise of arms from their infancy. Besides the janisaries, there is another body of foot called *capis*. The whole Turkish army, regulars and irregulars, amounts to above 300,000 men. Besides the true janisaries, or janisaries of the porte, and in actual pay, there are great numbers all over the empire, who procure themselves to be registered in this body, in order to be entitled to their privileges. The bachelors only are capable of bearing offices in the barracks or chambers at Constantinople. When any of the janisaries are disabled in the service, they have an allowance for life. To distinguish them, they wear a cap of a particular make. The emperor's guards are composed of them, and they are feared and respected every where, though they carry only a cane in their hand; for arms are not delivered to them but when they take the field. The chief commanders of the army are distinguished by two or three horse-tails carried before them. The Turkish navy is not so considerable as might be expected in such extensive dominions, situated on several seas, and abounding in commodious harbours. By their neglecting navigation and foreign commerce, they can never find sailors to man a great fleet; and those they have are unskilful, as well as their pilots and officers. If they would apply themselves to navigation, and make the most of their situation and advantages, they could not fail to become a very formidable maritime power. Their navy generally consists of about 40 large ships, exclusive of galleys. In time of war they hire or buy merchant-ships, and others are sent them from Algiers, Tunis, and Tripoli. The captain-bassa, or admiral, is the second officer in the empire, the grand vizir being the only officer above him. His power is absolute when he is out of the Dardanelles; and not only the sea-officers, but all the governors of the maritime provinces, receive orders from him. The pilots are mostly Greeks, and the captains renegadoes. The captain-bassa sails round the Archipelago, in summer, to collect the capitation-tax, and learn the state of affairs in those parts.

88

Revenues.

The revenues of the empire are paid either into the public treasury, or into the sultan's private treasury. The former, called by the Turks *deitulumali mufsimim*, i. e. *the public money of the Mussulman*, is not to be touched but on the most pressing exigency of the state. The other the sultan may dispose of at pleasure. Prince Cantimir says, in his time, 27,000 purses, amounting to 13,000,000 and a half of crowns, were annually returned to both treasuries; arising from the produce of the customs, demesne lands, the capitation or tax paid by every subject of the empire who is not of the Mahometan religion; the annual tributes paid by the chám of the Crim Tartars, the princes of Moldavia, Wallachia, the little republic of Ragusa, and part of Mingrelia; together with half a million of money out of a million and a half levied annually in Egypt. These are the fixed revenues: but vast sums are also raised by the confiscations of the estates and effects of the bassas and other officers, and from the estates of Turks dying without male issue.

89

Manufactures and commerce.

The manufactures and commodities of Turkey are silks, carpets, goat's hair, wool, camel's hair, cotton-yarn, dimity, burdets, waxed linen, shagreen-skins,

blue, red, and yellow Morocco leather; coffee, rhubarb, turpentine, florax, gums, opium, galls, mastic, emery, lemnian bole, pomegranate-shells, sponges, dates, almonds, wine, oil, figs, raisins, mother-of-pearl, boxwood, saffron, &c. These are exported in large quantities by the several European trading nations, who import their own goods and purchase those of the country. The inland trade is carried on chiefly by the Jews and Armenians; and even the Turks send merchandise, both by land and water, from one part of the empire to another, but not to foreign Christian countries. No nation is more advantageously situated for traffic than the Turkish; having the navigation of the Black Sea, the Levant, and the Red Sea, and consequently greater opportunities of importing the rich merchandises of the East, and distributing them all over Europe, than any maritime power: but they never attempt distant voyages, and have but few merchant-ships, both their imports and exports being chiefly made in foreign bottoms. Tyre, Sidon, and Alexandria, which once commanded the navigation and trade of the world, are in their possession, but make no figure in commerce at this day: and well it is for the Christians that the Turks are such an indolent generation; for their situation and vast extent of empire would enable them to monopolize the trade of the world, if they attended to it. Several European Christian nations have envoys and residents at Constantinople, and consuls in other ports. In this empire there is a great traffic in human species; not only male slaves, but beautiful young girls, being publicly bought and sold.

The empire is styled the Ottoman kingdom or empire, the Ottoman Porte, the Sublime Porte, the Sublime Sultanian Porte, &c. The appellation of *Porte* is said to be derived from the large gate built by Mohammed II. at the entrance of the seraglio at Constantinople; though the Orientals in general call a royal palace the *king's porte* or *gate*.

TURMERIC, in botany. See CURCUMA.

TURNERUS (Adrian), an eminent French critic, born of a genteel family in Normandy in 1512. He acquired so extensive a reputation by his learning, that he had great offers made him from Italy, Germany, and England; but we are told he preferred poverty in his own country to riches in any other. He taught polite literature first at Toulouse; but in 1547 went to be Greek professor at Paris, whither his name drew scholars to him from all parts of Europe: in 1552, he took upon him the care of the royal Greek press for three years, when he quitted it on being admitted into the number of royal professors. He died in 1565; and his works, which are all in Latin, were printed at Strasburg, in one vol. folio, 1600. His *Adversaria*, 3 vols folio, had been printed at Paris before.

TURETIN (Francis), minister and professor of divinity at Geneva, his native place, was born in 1623. Having studied at Geneva, Leyden, Saumur, Montauban, and Nîmes, with great success, he was admitted into the ministry in 1648, and served at the same time the French and Italian churches at Geneva. Two years after, he was offered the professorship of philosophy, which he refused; but accepted the invitation of the church of Lyons. He was recalled to Geneva at a year's expiration, because he was wanted to give lectures of divinity; and began them in 1653. He was sent to Holland in 1661, to desire the assistance of money which the city of Geneva had occasion for. He had in that journey all the success he could promise himself; and gained such a character there, that he was strongly importuned by the Walloon churches at the Hague and at Leyden to enter into their service. On his return he resumed the functions of his place, and continued there till his death with remarkable application. He died in 1687, with the character of a man of great merit; eloquent, judicious, laborious, learned, and zealous for orthodoxy. His works were published by his son John Alphonfus, in 3 and in 4 vols 4to, and are much esteemed.

TURTLE, in ichthyology. See TESTUDO.

TUSCAN ORDER, in architecture. See ARCHITECTURE, n° 47.

TUSCAN Earth, a yellowish kind of bole dug in many parts of Italy, particularly about Florence, where there is a stratum of it eight or ten feet thick, at the depth of five or six feet from the surface. It has an astringent property.

TUSCANY, a duchy of Italy, which makes part of the ancient Etruria, excepting some small detached parts, is encompassed by a part of the Mediterranean, called here the *Tuscan Sea*; the ecclesiastical state; the duchy of Modena; and the republic of Lucca; its extent from north to south being about 116 English miles, and from east to west about 80.

Though some parts of it are mountainous, yet both the hills and dales are covered with vines, olives, citron, lemon, and orange trees, &c. The mountains yield also copper, iron, alum, &c. and some quarries of the finest marble and porphyry. Here is also plenty of corn, rice, saffron, honey, wax, wool, flax, hemp, with mineral waters, rich pasture, salt-pits, sulphur, alabaster, chalcedony, lapis lazuli, borax, amethysts, cornelians, jaspers, quicksilver, crystals, and black slate. In some places the elms and ashes yield manna.

The principal river in Tuscany is the Arno, which has its source in the Appennine mountains, and falls into the sea below Pisa. There are some other smaller rivers.

This duchy fell under the dominion of the Romans about 455 years before Christ. The Ostrogoths possessed themselves of it in the fifth century, and after them the Lombards, who were expelled by Charlemagne anno 800, in consequence of which it became subject to the German emperors, who appointed governors over it. At last the cities of Florence, Pisa,

Sienna, and some others, during the contentions between the pope and the emperor, and their respective adherents, the Guelphs and Gibbelines, withdrew themselves into separate commonwealths. In that of Florence, John de Medicis, a popular nobleman, so influenced himself into the favour of his countrymen, that that they invested him with sovereign power. Pope Pius V. conferred the title of grand duke on Cosmo de Medicis anno 1570, in whose family the duchy continued until the death of Gaston de Medicis, who died anno 1737. The duchy was then transferred to the duke of Lorraine, the late emperor, in lieu of the duchy of Lorraine, which, by the peace of 1736, was given to king Stanislaus during his life, and then was to be annexed to France. The grand duke's annual revenues are computed at about 500,000 l. sterling, arising chiefly from the tenths of all estates that are sold or alienated, and the ground-rents of the houses in Leghorn, and the duties on almost all manner of provisions.

The great duke is absolute in his dominions. His standing forces consist only of three regiments of foot and two of dragoons, and his marine of a few galleys and galleasses; but, in case of necessity, it is said he can bring 30,000 men into the field, and increase his marine with 20 men of war; but it does not appear how he can man them.

The only order of knighthood in this state is that of St Stephen, instituted in 1554 by Cosmo I. which consists of three classes, namely, the Cavalieri della Gualtaria, della Graticia, and de Commenderie. The duke is always grand-master; and the badge of the order an octagonal red cross, with a golden border, worn on the breast.

The principal places are Florence, Pisa, Leghorn, Sienna, Orbitello, Piombino, and Arezzo.

TUSK, or TORSK, in ichthyology. See GADUS.

TUSCULANUM, a villa belonging to Cicero, near Tusculum, where he wrote his *Quæstiones Tusculanae*, so named from the place; thus become famous as well for the productions of genius as of nature. Formerly the villa of Sylla: now called *Grotta Ferrata*.—Another *Tusculanum*, (inscription), a town of the Transpadana, situated on the west side of the Lacus Benatus. Now said to be called *Tuscolano*, in the territory of Breſcia, subject to Venice. Here many monuments of antiquity are dug up.

TUSCULUM, (anc. geog.), a town of Latium, to the north of Alba; situated on an eminence, and therefore called *Supernum*, (Horace, Strabo). In sight of Rome, at about the distance of 100 stadia, or 12 miles. Adorned with plantations and princely edifices: The spot remarkable for the goodness of the soil, and its plenty of water. Built by Telegonus, who slew his father Ulysses, (Ovid, Horace); called the grandson of Ulysses in Silius Italicus. A municipium, (Cicero); the birth-place of the elder Cato, (Nepos, Cicero). Now *Frescati*, in the Campania of Rome.

TUSSILAGO, COLTS-FOOT, a genus of the polygamia superflua order, belonging to the syngenesia class of plants. There are nine species; of which the most remarkable are, 1. The farfara, or common colts-foot, growing plentifully on the banks of rivulets, or in

Tuscany
Tusillago

Tutor
||
Tweed.

in moist and clayey soils, in England and Scotland.—The leaves are smoked in the manner of tobacco, or a syrup or decoction of them and the flowers stand recommended in coughs and other disorders of the breast and lungs. The present practice, however, seems almost entirely to have rejected it. The downy substance under the leaves, boiled in a lixivium with a little saltpetre, makes excellent tinder. 2. The petasites, or common butter-bur, is frequent in wet meadows and by the sides of rivers. Its leaves are the largest of any plant in Great Britain, and in heavy rains afford a seasonable shelter to poultry and other small animals. The root dug up in the spring is resinous and aromatic. A drachm of it in a dose has been sometimes given as a sudorific and alexipharmic; but as it possesses those virtues but in a small degree, it has lost its reputation in the shops.

TUTOR, in the civil law, is one chosen to look to the persons and estate of children left by their fathers and mothers in their minority. A person nominated tutor either by testament or by the relations of the minor, is to decline that office if he have five children alive; if he have any other considerable tutorage; if he be under 25 years of age; if he be a priest or a regent in an university; or if he have any law-suit with the minors, &c. The marriage of a pupil without the consent of his tutor is invalid. Tutors may do any thing for their pupils, but nothing against them; and the same laws which put them under a necessity of preserving the interest of the minors, put them under an incapacity of hurting them.

TUTTY, *tutia*, a recreation of mixed metals, in which lapis calamarinus, or zinc in its metallic form, is an ingredient, collected in the furnaces where brass is made from copper and calamine, and where the mixed metals are run. In these furnaces they place, under the roof and about the upper parts of the sides, rods of iron, and sometimes rolls of dry earth, about which the tutty is afterwards found. Therefore the tutty which we use in the shops at this time owes its origin truly and properly to zinc, which sublimes with a very small fire into a kind of flowers; and when fused with any other metal, flies from it in abundance under this form, and also frequently takes some part of that metal, more or less, up with it. Hence it is evident, that the tutty or cadmia of the ancients must have been wholly different from ours, as they used no zinc nor any of its ores in the furnace where they collected it.

Our tutty, then, is a hard and heavy femetallie recreation, sometimes met with in the shops in thin flat pieces or flakes; but most abundantly in tubular cylindrical pieces, resembling segments of the barks of trees pushed off from the branches without breaking; these are of different lengths and diameters. The finest tutty is that of a fine deep brown on the outside, and of a yellowish tinge within; the thickest, brightest, and most granulated; the hardest to break; and that which has least foulness amongst it.

Tutty is celebrated as an ophthalmic, and frequently employed as such in unguents and collyria.

TWEED, a river of Scotland, which rises on the confines of the shire of Clydesdale, and running eastward through Tweedale, and dividing the shire of Mers from Teviotdale and Northumberland, falls into the German Sea at Berwick.

Tweedale
||
Twilight.

TWEEDALE, or PEEBLES, a county of Scotland, taking the name of Tweedale from the river Tweed, that runs through the whole length of the county, stretches about 25 miles in length, and at some places 18 in breadth; bounded on the east by Ettrick Forest, on the south by Annandale, on the west by Clydesdale, and on the north by Mid-Lothian. Tweedale is a hilly country, well watered with the Tweed, the Yarrow, and a great number of smaller streams, that fertilize the valleys, which produce good harvests of oats and barley, with some proportion of wheat. All the rivers of any consequence abound with trout and salmon. The lake called *West-Water Loch*, swarms with a prodigious number of eels. In the month of August, when the west wind blows, they tumble into the river Yarrow in such shoals, that the people who wade in to catch them run the risk of being overturned. There is another lake on the borders of Annandale, called *Lochgennen*, which forms a cataract over a precipice 250 paces high: here the water falls with such a momentum as to kill the fish underneath. About the middle of this county is the hill or mountain of Braidalb; from the top of which the sea may be seen on each side of the island. Tweedale abounds with limestone and freestone. The hills are generally as green as the downs in Suffolk, and feed innumerable flocks of sheep, that yield great quantities of excellent wool. The country is well shaded with woods and plantations, abounds with all the necessaries of life, and is adorned with many fine seats and populous villages. The earls of March were hereditary sheriffs of Tweedale, which bestows the title of *marquis* on a branch of the ancient house of Hay, earls of Errol, and hereditary high constables of Scotland. The family of Tweedale is, by the female side, descended from the famous Simon de Fraser, proprietor of great part of this country, who had a great share in obtaining the triple victory at Rosslin. In the neighbourhood of Peebles, near the village of Romana, on the river Lene, we see the vestiges of two Roman castella, or stationary forts; and a great many terraces on the neighbouring hills, which perhaps have served as itinerary encampments. In the shire of Tweedale there are many ancient and honourable families of the gentry. Among these Douglas of Cavers, who was hereditary sheriff of the county, still preserves the standard and the iron mace of the gallant lord Douglas, who fell in the battle of Otterburn, just as his troops had defeated and taken Henry Percy, surnamed *Hotspur*. In the church-yard of Drumalzier, belonging to an ancient branch of the Hay family, the famous Merlin is supposed to lie buried. There was an old traditional prophecy, that the two kingdoms should be united when the waters of the Tweed and the Panfel should meet at his grave. Accordingly the country people observe, that this meeting happened in consequence of an inundation, at the accession of James VI. to the crown of England.

TWELETH-DAY, the festival of the Epiphany, or the manifestation of Christ to the Gentiles; so called, as being the twelfth day, exclusive, from the nativity, or Christmas-day.

TWILIGHT, that light, whether in the morning before sun-rise, or in the evening after sun-set, supposed to begin and end when the least stars that can be seen

Tinkling
Tyndale.

Tyndale,
Type.

by the naked eye cease or begin to appear. By means of the atmosphere, it happens that though none of the sun's direct rays can come to us after it is set, yet we still enjoy its reflected light for some time, and night approaches by degrees. For after the sun is hid from our eyes, the upper part of our atmosphere remains for some time exposed to its rays, and from thence the whole is illuminated by reflection. But as the sun grows lower and lower, that portion of the atmosphere which is above our horizon becomes enlightened till the sun has got 18° below it; after which it ceases to be illuminated thereby, till it has got within as many degrees of the eastern side of the horizon; at which time it begins to illuminate the atmosphere again, and in appearance to diffuse its light throughout the heavens, which continues to increase till the sun be up. Hence it is that during that part of the year in which the sun is never 18° below our horizon, there is a continued twilight from sun-setting to sun-rising.

As the twilight depends on the quantity of matter in the atmosphere fit to reflect the sun's rays, and also on the height of it; for the higher the atmosphere is, the longer will it be before the upper parts of it will cease to be illuminated, the duration of it will be various. For instance, in winter, when the air is condensed with cold, and the atmosphere upon that account lower, the twilight will be shorter; and in summer, when the limits of the atmosphere are extended by the rarefaction and dilatation of the air, of which it consists, the duration of the twilight will be greater. And for the like reason, the morning twilight, the air being at that time condensed and contracted by the cold of the preceding night, will be shorter than the evening one, when the air is more dilated and expanded.

TWINKLING of the STARS. See STARS.

TWINS, two young ones delivered at a birth, by an animal which ordinarily brings forth but one.

TYGER, or **TIGER**, in zoology. See FELIS.

TYLE, or **TILE**, in building, a sort of thin laminated brick used on the roofs of houses: or more properly a kind of fat clayey earth kneaded and moulded of a just thickness, dried and burnt in a kiln like brick, and used in the covering and paving of houses.

TYMPAN, among printers, a double frame belonging to the press, covered with parchment, on which the blank sheets are laid in order to be printed off. See **PRINTING-Press**.

TYMPANUM, in mechanics, a kind of wheel placed round an axis or cylindrical beam, on the top of which are two levers or fixed staves for the more easily turning the axis in order to raise a weight required. The tympanum is much the same with the peritrochium; but that the cylinder of the axis of the peritrochium is much shorter and less than the cylinder of the tympanum.

TYMPANUM, in anatomy. See there, n° 405, c.

TYMPANY, in medicine. See MEDICINE, n° 435.

TYNDALE (William), a learned divine, the first translator and publisher of the Old and New Testament in the English language, was born near the borders of Wales, and educated at Oxford, chiefly in Magdalen-hall. We are told that he was admitted a canon of the new college founded by Wolsey; but Anthony Wood disputes this fact. Having imbibed the opinions of Luther, and being apprehensive of persecution, he

removed to Cambridge, where he finished his academical studies. From thence he went to the house of Sir John Welch at Little Sodbury in Gloucestershire, in the capacity of tutor to that gentleman's children; and being then in orders, frequently preached at Bristol, and in that neighbourhood: but his doctrine being by the clergy of those times deemed heretical, he was obliged once more to fly from persecution. He now removed to London, where he preached for some time in St Dunstan's in the West. Having conceived an idea of bishop Tonstal's moderation from the character given him by Erasmus, he made an attempt to be admitted one of his chaplains; but not succeeding, and now destitute of support, he was taken into the house of Mr Humphrey Monmouth, alderman of London, where he continued about half a year. In this situation he first meditated the translation of the New Testament into English, as the most effectual means to bring about a reformation in religion; but as this could not be safely attempted in England, he embarked for Germany, supported by his friends with a pension of 10*l.* per annum. Having first paid a visit to Martin Luther, at that time in Saxony, he settled at Antwerp, and immediately began his translation of the New Testament, which was first printed in 1526, in 8vo. The gospel was always beholden to persecution for its propagation. The whole impression was in a short time consumed, and Tyndale: by that means enabled to publish a second much more numerous.

Having now finished his first work, the indefatigable Tyndale began his translation of the Old Testament; and the five books of Moses being ready for the press, he embarked for Hamburg with an intention to print them; but the ship being cast away, all his papers, books, and money, were lost. However, he arrived safe at Hamburg; where, with the help of Miles Coverdale, he began the work anew, and finished the Pentateuch, which was printed in 1530. To this he added the book of Jonas, which was published the year following.

The matter now grew serious. The Papists were alarmed; and Tyndale's translations were at all events to be suppressed. The most conscientious Defender of the Faith assembled the heads of the clergy in the star-chamber, and, with their approbation, issued his royal proclamation for the total extinction of the English Bible, with all other books containing pestilential and damnable heresies. The Bibles, as many as were brought in, were accordingly burnt: but this was not enough. To appease the offended genius of Popery, it was necessary that the translator himself should also burn. Poor Tyndale, in consequence of an application from the court of London, was seized by the emperor's procurator-general at Brussels, confined in the castle of Vilvorde, 18 miles from Antwerp; and after 18 months imprisonment, in the year 1536, condemned and executed. They had however the humanity to strangle him first; after which his body was reduced to ashes. Thus died this very honest and learned divine, for having translated and, as was falsely pretended, perverted the scriptures.

TYPE, a copy, image, or resemblance of some model. The word is much used among divines, to signify a symbol, sign, or figure of something to come; in which sense it is commonly used with relation to antitype,

Type
|
Tyrrhel. titype, which is the thing itself, whereof the other is a type or figure.

TYPE, among letter-founders and printers, the same with letter. See LETTER.

TYPE is also used to denote the order observed in the intention and remission of fevers, pulses, &c.

TYPHA, CAT'S TAIL; a genus of the triandria order, belonging to the monocia class of plants. There are two species; of which the most remarkable is the latifolia, great cat's-tail or reed-mace, frequent in ponds and lakes. The stalk is six feet high; the leaves a yard long, hardly an inch wide, convex on one side: the amentum, or cylindrical club, which terminates the stalk, is about six inches long, of a dark brown or fuscous colour. Cattle will sometimes eat the leaves, but Schröber thinks them noxious: the roots have sometimes been eaten in salads, and the down of the amentum used to stuff cushions and mattresses. Linnaeus informs us, that the leaves are used by the coopers in Sweden to bind the hoops of their casks.

TYPHON. See WHIRLWIND.

TYPOGRAPHY, the art of printing. See PRINTING.

TYRANNION, a celebrated grammarian in Pompey's time, was of Amisus in the kingdom of Pontus. He was the scholar of Dionysius of Thrace at Rhodes. He fell into the hands of Lucullus, when that general of the Roman army defeated Mithridates, and seized his dominions. This captivity of Tyrannion was no disadvantage to him, since it procured him an opportunity of being illustrious at Rome, and raising a fortune. He spent it, among other things, in making a library of above 30,000 volumes. He died very old, being worn out with the gout. His care in collecting books contributed very much to the preservation of Aristotle's works.

TYRANT, among the ancients, denoted simply a king or monarch; but the ill use which several persons invested with that sacred character made of it, has altered the import of the word; and tyrant now carries with it the idea of an unjust or cruel prince, who invades the people's liberty, and rules in a more despotic manner than the laws of nature or of the country allow.

TYRE. See TYRUS.

TYRONE, a county of Ireland, in the province of Ulster, 46 miles in length, and 37 in breadth; bounded on the north by Londonderry, on the east by Armagh and Lough-Neagh, on the south by Fermanagh, and on the west by Donnegal. It is a rough and rugged country, but tolerably fruitful; contains 12,683 houses, 30 parishes, 4 baronies, 4 boroughs, and sends 10 members to parliament. The principal town is Dungan-non.

TYRREL (James), author of a history of England, was the eldest son of Sir Timothy Tyrrel of Shot-over, near Oxford, and born in London in 1642. He was educated at queen's college in Oxford, where he took his degrees; and removing thence to the Inner Temple in London, applied himself to the study of the

law, but never practised. He employed himself in studying the history and constitution of his country, of which he at length rendered himself a thorough master, as appears from his answer to Sir Robert Filmer, and his Political Dialogues; as also from his History of England, which reaches no farther than the end of the reign of king Richard II. He died in 1718.

TYRTEUS, an Athenian general and musician, is celebrated by all antiquity for the composition of military songs and airs, as well as the performance of them. He was called to the assistance of the Lacedæmonians in the second war with the Messenians, about 685 B. C.; and a memorable victory which they obtained over that people is attributed by the ancient scholiasts upon Horace to the animating sound of a new military flute or clarion, invented and played upon by Tyrteus. Plutarch tells us that they gave him the freedom of their city; and that his military airs were constantly sung and played in the Spartan army to the last hour of the republic. And Lycurgus the orator, in his oration against Leocrates, says, "The Spartans made a law, that whenever they were in arms, and going out upon any military expedition, they should all be first summoned to the king's tent to hear the songs of Tyrteus;" thinking it the best means of sending them forth in a disposition to die with pleasure for their country. Fragments of this poetry, in elegiac verse, are preserved in Stobæus, Lycurgus Orat. in Fulvius Ursinus, at the end of Poems by illustrious Women; and in the Oxford edition of *Eleg. & Lyric. Frag. & Scholia*, printed 1759. Τα Τυρτείου, &c.

TYRUS, a very famous and ancient city of Phœnicia, built by the Sidonians, (Justin); consequently of a later date than Sidon. No mention made of Tyre before David's time; none by Homer, who mentions Sidon and the Sidonians, (Strabo). Tyre was a very large rich city, and powerful at sea, the rival of Sidon: formerly situated on an island; but after the time of Alexander, on the continent, or in a peninsula, formed by Alexander's mole or causeway, thrown up at the siege of it, (Curtius, Ovid, Strabo). Famous for its colonies, both within and without the pillars of Hercules, (Strabo, Pliny); and its purple dye. In Hebrew called *Zor* or *Sor*; and, according to another dialect, *Syr*, *Sar*; whence the adjoining country was called *Syria*; and by the Armenians or Syrians, *Tor*, *Tur*, *Tyr*, and with a Greek termination, *Tyres*; also *Sarra*. Their principal deity was Hercules, which Nonnus says was the sun; called *Hercules Tyrius*, (Diodorus); and Tyre itself was called *Tyrus Eractia*, (Coins). Out of a regard to its fame and antiquity, it enjoyed its liberty both under the Seleucidæ and the Romans, (Strabo); it also received a Roman colony, and was then called *Colonia Septimia*, (Coins). Of Tyre were Porphyry, the famous antagonist of Christianity; Maximus, the Platonic philosopher; and Ulpian, the celebrated civilian. Now commonly called *Tyre*, a port-town on the coast of the Levant. E. Long. 36°. N. Lat. 32. 32.

Tyrteus.
Tyros.

U, V.

U
Vaccinium.

U, or *u*, the 20th letter and 5th vowel of our alphabet, is formed in the voice by a round configuration of the lips, and a greater extrusion of the under one than in forming the letter *o*, and the tongue is also more cannulated. The sound is short in *curst*, *must*, *tun*, *tub*; but is lengthened by a final *e*, as in *tune*, *tube*, &c. In some words it is rather acute than long; as in *brute*, *fute*, *lute*, &c. It is mostly long in polysyllables; as in *union*, *curious*, &c. but in some words it is obscure, as in *nature*, *venture*, &c. This letter in the form of *V*, or *v*, is properly a consonant, and as such is placed before all the vowels; as in *vacant*, *venal*, *vibrate*, &c. Though the letters *v* and *u* had always two sounds, they had only the form *v* till the beginning of the fourth century, when the other form was introduced, the inconvenience of expressing two different sounds by the same letter having been observed long before. In numerals *V* stands for five; and with a dash added at top, thus *Ṽ*, it signifies 5000.

In abbreviations, amongst the Romans, *V. A.* stood for *veterani assignati*; *V. B. viro bono*; *V. B. A. viri boni arbitratus*; *V. B. F. vir bone fidei*; *V. C. vir consularis*; *V. C. C. F. vale, conjux charissime, felicitate*; *V. D. D. voto delicatus*; *V. G. verbi gratia*; *Vir. Ve. virgo vestalis*; *VL. videlicet*; *V. N. quinto nonarum*.

VACCINIUM, the WHORTLEBERRY, or *Bilberry*; a genus of the monogynia order, belonging to the octandria class of plants. There are 12 species; of which the most remarkable are, 1. The myrtillus, black-whortle, whortle-berries, or bilberries, growing in woods and on heaths abundantly. The flowers frequently vary, with five segments at the rim, and with ten stamina. The berries when ripe are of a bluish black colour; but a singular variety, with white berries, was discovered by his grace the duke of Athol, growing in the woods, about mid-way between his two seats of Dunkeld and Blair. The berries have an astringent quality. In Arran and the Western Isles they are given in diarrhoeas and dysenteries with good effect. The Highlanders frequently eat them in milk, which is a cooling agreeable food; and sometimes they make them into tarts and jellies, which last they mix with whiskey to give it a relish to strangers. They dye a violet colour; but it requires to be fixed with alum. The grouse feed upon them in the autumn.

2. The uliginosum, or great bilberry-bush, is found in low moist grounds, and almost at the summits of the Highland mountains, as upon Crag-Chailleach in Breadalbane, upon the higher hills about Loch-Rannoch in Athol, upon the mountains of Ross-shire, about Loch-Broom, and Inverness-shire about Loch-Urn, &c. and in the low boggy grounds of the island of Mull, and near the duke of Argyle's, at Inverary, &c. The leaves are full of veins, smooth and glaucous, especially on the under side; the berries are eatable, but not so much esteemed as the preceding; as they are apt, if eaten in any quantity, to give the headach.

3. The *vitis idæa*, or red whortle-berries, being fre-

quent in dry places in heaths, woods, and on mountains. The berries have an acid cooling quality, useful to quench the thirst in fevers. The Swedes are very fond of them made into the form of a rob or jelly, which they eat with their meat as an agreeable acid, proper to correct the animal alkali.

4. The oxycoccos, cran-berries, moss-berries, or moor-berries, frequent on peat-bogs in the Lowlands, but not so common in the Highlands of Scotland. The stalks are long, slender, woody, weak, and trailing; the leaves are stiff, acutely oval, glaucous underneath, their edges turned back, and grow alternate; two or three flowers grow singly on long red footstalks out of the extremity of the branches; the flowers are red, divided deeply into four acute segments, which are reflexed quite backwards; the filaments are downy, the anthers ferrugineous, and longer than the filaments: the berries red, and about the size of the hawthorn-berries. At Longtown, on the borders of Cumberland, they are made so considerable an article of commerce, that, at the season when they are ripe, not less than 20l. or 30l. worth are sold by the poor people each market-day for five or six weeks together, which are afterwards dispersed over different parts of the kingdom, for making the well-known cranberry tarts.

VACUUM, in philosophy, denotes a space empty or devoid of all matter or body.

It has been a matter of much dispute among philosophers, whether there is a possibility of producing in nature a perfect vacuum, or space void of all body whatever. The Cartesians have violently contended against the possibility of this; while the Newtonians have argued as strenuously, not only for the possibility, but even the actual existence of a vacuum. In some instances, however, the arguments on both sides have been very inconclusive. The Cartesians have argued, from the ascent of water in pumps, that nature abhorred a vacuum. The Newtonians have disproved this by showing that the ascent of water in those machines is owing to the pressure of the atmosphere, and cannot be extended beyond a certain space. In like manner the limited ascent of mercury in a barometer, shows that it is occasioned only by the pressure of the atmosphere, and not by any power of suction or abhorrence of a vacuum, which would be equivalent to the pressure of any column of mercury, however high. Another argument in favour of a vacuum is drawn from the motions of the celestial bodies, meeting with no apparent resistance in the heavenly spaces. As no body with which we are acquainted can move through a fluid without sensible resistance, Sir Isaac Newton concludes, for the reason above-mentioned, that "it is necessary the celestial spaces be void of all matter, excepting perhaps some few and much rarefied effluvia of planets and comets, and the passing rays of light." An argument of the same kind is deduced from the motion of pendulums in an exhausted receiver meeting with no sensible resistance from the medium therein contained.—Sir Isaac also contends, that the descent of gravi-

Vaccinium,
Vacuum.

gravitating bodies proves the existence of a vacuum. "If all spaces (says he) were equally full, the specific gravity of that fluid with which the region of the air would in that case be filled, would not be less than the specific gravity of quicksilver or gold, or any other the most dense body; and therefore neither gold, nor any other body, could descend therein.—For bodies do not descend in a fluid, unless that fluid be specifically lighter than the body.—But by the air-pump we can exhaust a vessel, till even a feather shall fall with a velocity equal to that of gold in the open air: the medium, therefore, through which the feather falls must be rarer than that through which the gold falls.

"The quantity of matter, therefore, in a given space, may be diminished by rarefaction: and why may not it be diminished in *infinitum*? Add, that we conceive the solid particles of all bodies to be of the same density: and that they are only rarefiable by means of their pores; whence a vacuum evidently follows."

The strongest argument, however, for a vacuum, perhaps is, that we cannot have any idea of the possibility of motion without a vacuum. The force of this argument will be increased from the two following considerations. 1. That all motion is either in a straight line, or in a curve which returns into itself, as the circle and ellipsis; or in a curve that does not return into itself, as the parabola, &c. And, 2dly, that the moving force must always be greater than the resistance.

For hence it follows, that no force, even though infinite, can produce motion where the resistance is infinite; consequently, there can be no motion either in a straight line or a non-returning curve; because, in either of those cases, the protrusion, and consequently the resistance, would be infinite.—There remains, therefore, only the motion in a revolving curve practicable; which must either be a revolution upon an axis, or an angular motion round a quiescent body; both which are, again, impossible in an elliptic curve: and consequently all motion must be in circles geometrically true; and the revolving bodies must either be spheres, spheroids, cylinders, or portions of them, exactly geometrical; otherwise their revolutions in a plenum would be impossible: but such motions, or such figured bodies, we do not know in nature. Therefore there is a vacuum.

Again, say these philosophers, that there are interspersed vacuities, appears from matter's being actually divided into parts, and from the figures of those parts: for, on supposition of an absolute plenitude, we do not conceive how any part of matter could be actually divided from that next adjoining, any more than it is possible to divide actually the parts of absolute space from another: for by the actual division of the parts of a continuum from one another, we conceive nothing else understood, but the placing those parts at a distance from one another, which, in the continuum, were at no distance from one another; but such divisions between the parts of matter must imply vacuities between. As for the figures of the parts of bodies, upon the supposition of a plenum, they must either be all rectilinear, or all concavo-convex, otherwise they would not adequately fill space; which we do not

find to be true in fact. Lastly, The denying a vacuum, supposes what it is impossible for any one to prove to be true, viz. that the material world has no limits.

To every one of these arguments, however, the assertors of a plenum, now, when assisted by the discoveries concerning the electric fluid, are able to give pretty satisfactory answers. In the cases of pumps of all kinds they contend, that the space once occupied by the air is instantly filled up by the electric fluid which flows in through the sides of the receiver, or otherwise during the time the air is extracting; and they are able to give proofs of the existence of this fluid even in the most perfect vacuum which we can make. With regard to the celestial motions it is contended, that the fluids of light and electricity are the same, and that though, by means of this ethereal fluid, a very violent resistance might be occasioned, yet were its strength and agility applied to the purposes of giving motion, there is not the least doubt that every one of the celestial motions might be continued by its means; and that not only *might* this be the case, but there are strong reasons for believing that it actually *is* so.

The arguments drawn from the descent of bodies, they also contend, are inconclusive. There can only, they say, be two sources of resistance to a body moving through a fluid; one is the friction of the parts of the fluid upon one another, and the other when the fluid itself has a tendency to move in a direction contrary to the moving body. If we suppose the fluid to be totally devoid both of friction, and of any tendency to move towards a centre or otherwise, it not only can make no resistance to motion, but if once a motion is begun in it, it will continue it for ever. Therefore, in the case of pendulums vibrating in an exhausted receiver, they contend, that the medium in which they move, though equally *dense* as before, is yet much more devoid of gravity and of friction than the common atmosphere, and therefore the resistance of it is much less; whence the vibrations of the pendulum are much longer continued than in the open air.—The advocates for a plenum also deny that rarefaction implies a diminution of the quantity of matter in any body. They contend, that there are two kinds of matter, one of which is subject to the laws of gravity, and the other not; consequently, if bodies are compounded of those two kinds of matter, they will to us appear to be rare or dense, as the one or the other kind prevails.

As to the arguments taken from the nature of motion, we know not the figure, nor indeed, when we come to examine the subject strictly, can we have any idea of the ultimate component particles of matter; so that we must relolve every thing into the action of infinite wisdom and power in the construction of the universe. If the particles of matter are infinitely divisible, according to one of Sir Isaac Newton's suppositions; then they must yield to motion in every direction as easily as if nothing was present, provided the body moved with force sufficient to break them; and this force we may, indeed, we must suppose to be *infinitely small*. If, according to another of Sir Isaac Newton's hypotheses, we suppose matter to be composed of solid hard particles which cannot be broken

Vacuum.

by any power whatever, then indeed these particles must have a certain determinate figure, either spherical, concavo-convex, or some other which perhaps has not occurred to human ingenuity. If they are spheres, we are then sure that there must be what is called a *vacuum disseminatum* or *interspersum* equal to the whole quantity of matter in the universe. But there is no necessity for supposing this; nor will our inability to produce motion, or to know how it can be produced, ever be an argument for its being done in this or that particular way; nor can we at all argue with regard to the figure of the component parts of matter, or concerning the bounds of the universe; our faculties being limited to those things which are the objects of our senses, either naturally or by some kind of similitude.

It has been observed of late, that in the most perfect vacuum which can be produced, not only in an air-pump, but even in the upper part of a barometer, evaporation both of water and of mercury takes place: it may not be amiss to inquire into the manner in which this process can be supposed to go on. The phenomenon has already been taken notice of under the article *EVAPORATION*, n° 5, and may receive a satisfactory explanation on the principles there laid down. It is there proved, that all kinds of vapour consist of an union of the principle of heat with the evaporating substance. In consequence of this union the vapours are exceeding light; and because fire may well be supposed devoid of gravity altogether, therefore they will rise till they come to a region where the medium is of equal gravity with their own. In rarefied air the vapours will still rise, though the proportion of heat they have in them must then be greater, to make them ascend in a medium of so little specific gravity. It would seem therefore, that even the medium left behind the mercury when sinking down in the barometer is still somewhat heavier than extremely subtle vapours, as they will arise even in that medium, and condense on the upper part of the tube.—It is natural to suppose that the quantity of heat contained in these vapours is very great in proportion to the quantity of terrestrial matter they contain.

Vacuum, or *Vacuum Boyleanum*, is also used to express that approach to a real vacuum which we are supposed to arrive at by means of the air-pump. See *AIR-PUMP*. Thus, any thing put in a receiver so exhausted, is said to be put *in vacuo*: and thus most of the experiments with the air-pump, are performed *in vacuo*, or *in vacuo Boyleano*.

Some of the principal phenomena observed of bodies in *vacuo* are, that the heaviest and lightest bodies, as a guinea and a feather, fall here with equal velocity: That fruits, as grapes, cherries, peaches, apples, &c. kept for any time in *vacuo*, retain their nature, freshness, colour, &c. and those withered in the open air, recover their plumpness in *vacuo*:—All light, and fire, becomes immediately extinct in *vacuo*:—The coalition of flint and steel in *vacuo* produces no sparks:—No sound is heard even from a bell rung in *vacuo*:—A square viol, full of common air, well closed, breaks in *vacuo*; a round one does not:—A bladder half full of air, will heave up forty pound weight in *vacuo*:—Cats, and most other animals, readily expire in *vacuo*.

By experiments made in 1704, Mr Derham found,

that animals which have two ventricles, and no foramen ovale, as birds, dogs, cats, mice, &c. die in less than half a minute; counting from the first excution: a mole died in one minute, a bat lived seven or eight.—Insects, as wasps, bees, grasshoppers, &c. seemed dead in two minutes; but, being left in *vacuo* 24 hours, came to life again in the open air: snails continued 24 hours in *vacuo*, without appearing much concerned.

Seeds planted in *vacuo* do not grow:—Small-beer dies, and loses all its taste in *vacuo*:—Lukewarm water boils very vehemently in *vacuo*:—Air, rushing through mercury into a vacuum, throws the mercury in a kind of shower upon the receiver, and produces a great light in a dark room.

The air-pump can never produce an entire extraction of the air, as is evident from its structure and the manner of its working: in effect, every excution only takes a part of the air; so that there will still be some left after any finite number of excutions.—Add, that the air-pump has no longer any effect, than while the spring of the air remaining in the receiver is able to lift up the valves: when the rarefaction is come to that degree, you can come no nearer to a vacuum. Sir Isaac Newton, observing that a thermometer suspended in *vacuo*, and in that state removed to a warm or a cold room, receives the heat or cold, rises or falls, almost as soon as another in open air, takes thence occasion to suspect that the heat of the warm room is conveyed through the vacuum by the vibrations, of a much subtiler medium than air, which remained in the vacuum after the air was drawn out.

VADIUM, a pledge in law, is either *vivum* or *mortuum*.

Vadium Vivum, or *Living Pledge*, is when a man borrows a sum (suppose 200*l.*) of another; and grants him an estate, as of 20*l.* *per annum*, to hold till the rents and profits shall repay the sum so borrowed. This is an estate conditioned to be void as soon as such sum is raised. And in this case the land or pledge is said to be living: it subsists, and survives the debts; and, immediately on the discharge of that, returns back to the borrower.

Vadium Mortuum, or *Dead Pledge*. See *MORTGAGE*.

VAGABOND, or *VAGRANT*, one who wanders illegally, without a settled habitation. Such persons are cognizable by the laws. See *IDLENESS*.

VAGINA, properly signifies a sheath or scabbard; and the term *vagina* is used in architecture for the part of a terminus, because resembling a sheath out of which the statue seems to issue.

VAGINA, in anatomy, a large canal, formed of a robust or strong membrane, and reaching from the external orifice, or os pudendi, of women, to the uterus.

VAILLANT (John Foy), a physician and great medalist, to whom, according to Voltaire, France was indebted for the science of medals, and Lewis XIV. for one half of his cabinet, was born at Beauvais in 1632. Through the means of the minister Colbert he travelled into Italy, Greece, Egypt, and Persia, to collect medals for the royal cabinet; and returned with so many as made the king's cabinet superior to any in Europe. In one of his voyages the ship he sailed in was fallen upon and taken by an Algerine corsair.

After

Vadium
||
Vailant.

After a captivity of near five months he was permitted to return to France, and received at the same time 20 gold medals, which had been taken from him. He embarked in a vessel bound for Marseilles, and was carried on with a favourable wind for two days, when another corsair appeared, which, in spite of all the fail they could make, bore down upon them within the reach of cannon-shot. Mr Vaillant, dreading the miseries of a fresh slavery, resolved, however, to secure the medals which he had received at Algiers, and in order thereto swallowed them. But a sudden turn of the wind freed them from this adversary, and cast them upon the coasts of Catalonia; where, after expecting to run aground every moment, they at length fell among the sands at the mouth of the Rhone. Mr Vaillant got to shore in a skiff, but felt himself extremely incommoded with the medals he had swallowed, which might weigh altogether five or six ounces, and therefore did not pass like Scarborough waters. He had recourse to a couple of physicians, who were a little puzzled with the singularity of his case; however, nature relieved him from time to time, and he found himself in possession of the greatest part of his treasure when he got to Lyons. Here he explained, with much pleasure to his friends, those medals which were already come to hand, as well as those which were daily expected; among which last was an Otho, valuable for its rarity. He was much careless on his return; and when Lewis XIV. gave a new form to the academy of inscriptions in 1701, Mr Vaillant was first made associate, and then pensionary. He wrote several works relating to ancient coins, and died in 1706.

VAIR, or VAIRE, a kind of fur, formerly used for lining the garments of great men and knights of renown. It is represented in engraving by the figures of little bells reversed, ranged in a line; see HERALDRY, Pl. CLXIV, fig. 2. n° 15. Of this fur is sometimes formed a cross, a bend, &c. M. de la Colombière observes, that when furriers first made this lining, they used small pieces, most frequently of an azure colour, which they fitted to white furs; and he infers from that, that those who have settled the rules of heraldry decreed, in relation to vair, that this fur in its natural blazon should always be argent and azure; so that if it be said, such a family bears vair, it is supposed to be argent and azure; but if there be any other tincture, the same must be expressed, saying, such a family bears vair, or, and gules, or otherwise. The same author relates an account of this fur being first introduced into French armoury, but too tedious to be inserted here.

VAIRY, in heraldry, expresses a coat, or the bearings of a coat, when charged or chequered with vairs.

VALAIS, a valley in Switzerland, which extends from the source of the river Rhone to the lake of Geneva. It is near 100 miles in length, but the breadth is very unequal. It is bounded on the north by the Alps, which separate it from the cantons of Bern and Uri, on the east by the mountains of Forche, and on the south by the duchy of Milan and the Val d'Aoste, and on the west by Savoy and the republic of Geneva. The inhabitants profess the Roman-Catholic religion, and are subject to the swelling of the throat, called *bronchette*; and idiots are said to abound among them more than in any other place of the globe. They are naturally hardy, enterprising, and good-natured. It

is surrounded on all sides by very high mountains, most of which are covered with snow and ice, that never thaw. However, the soil is fertile in corn, wine, and good fruit. The muscat-wine, which is produced here, is excellent, and well known all over Europe. There are mineral waters, plenty of game, and some mines. This country comprehends 55 large parishes, to which one bishop only belongs, whose see is at Sion, the capital. The mountains afford good pasture for their cattle in summer, and their harvest continues from May to October; it being sooner or later, according to the situation of the place.

VALENCIA, a province of Spain, which has the title of a kingdom; and is bounded on the east and south by the Mediterranean sea, on the north by Catalonia and Aragon, and on the west by New Castile and the kingdom of Mercia. It is about 165 miles in length, and 63 in breadth. It is one of the most populous and agreeable parts of Spain, and where they enjoy almost a perpetual spring. The great number of rivers wherewith it is watered render it extremely fertile, particularly in fruits and wine. There are very rugged mountains in it, which contain mines of alum and other minerals.

VALENCIA, a city of Spain, and capital of the kingdom of the same name. It contains about 12,000 houses, besides those of the suburbs and the summer-houses round it. It has an university, and an archbishop's see; and was taken from the Moors by the Christians in the 13th century. The town is handsome, and adorned with very fine structures. It is not very strong, though there are some bastions along the sides of the walls. They have manufactures in wool and silk, which bring in great sums to the inhabitants. It is seated on the river Guadalquivir, over which there are five handsome bridges; and it is about three miles from the sea, where there is a harbour, 110 miles north of Murcia, and 165 east by south of Madrid. This city surrendered to the earl of Peterborough in the year 1705; but it was lost again in 1707. W. Long. o. 5. N. Lat. 39. 30.

VALENS (Flavius), emperor of the East, a great patron of the Arians. Killed by the Goths in the year 379. See CONSTANTINOPLE, n° 74—80.

VALENTINIAN I. emperor of the West, a renowned warrior, but a tyrant over his subjects. See ROME, n° 523.

VALENTINIAN II. emperor of the West, a prince celebrated for his virtues, and above all for his moderation; yet a conspiracy was formed against him by Arbogastes, the commander in chief of his armies; and he was strangled in the year 392. See ROME, n° 536.

VALENTINIANS, in church-history, a sect of Christian heretics, who sprung up in the second century, and were so called from their leader Valentinus.

The Valentinians were only a branch of the Gnostics, who realized or personified the Platonic ideas concerning the Deity, whom they called *Pleroma*, or *Plenitude*. Their system was this: the first principle is Bythos, *i. e.* Depth, which remained many ages unknown, having with it Ennoia, or Thought, and Sige, or Silence; from these sprung the Nous, or Intelligence, which is the only son, equal to and alone capable of comprehending, the Bythos; the filer of Nous they called *Altheia*, or *Truth*; and these constituted the first quarter-

Valerian
||
Valerius

quaternity of the æons, which were the source and original of all the rest: for Nous and Aletheia produced the World and Life; and from these two proceeded Man and the Church. But besides these 8 principal æons, there were 22 more, the last of which, called *Sophia*, being desirous to arrive at the knowledge of Bythos, gave herself a great deal of uneasiness, which created in her Anger and Fear, of which was born Matter. But the Horos, or Bounder, stopped her, preserved her in the Pleroma, and restored her to perfection. *Sophia* then produced the Christ and the Holy Spirit, which brought the æons to their last perfection, and made every one of them contribute their utmost to form the Saviour. Her Enthemse, or Thought, dwelling near the Pleroma, perfected by the Christ, produced every thing that is in the world by its divers passions. The Christ sent into it the Saviour, accompanied with angels, who delivered it from its passions, without annihilating it: from thence was formed corporeal matter. And in this manner did they romance concerning God, nature, and the mysteries of the Christian religion.

VALERIAN, or **VALERIANUS**, (Publius Licinius), emperor of Rome, remarkable for his captivity and cruel treatment by Sapor I. king of Persia. See *Rome*, n° 491.

VALERIANA, **VALERIAN**; a genus of the monogynia order, belonging to the triandria class of plants. There are 20 species; the most remarkable of which is the officinalis, or great wild valerian, growing naturally in Britain, in ditches, marshy places, and sometimes in dry mountainous pastures. The root is much used in medicine, and consists of a number of strings or fibres matted together, issuing from one common head; of a whitish or pale brownish colour: its smell is strong, like a mixture of aromatics with fetids; the taste unpleasantly warm, bitterish, and subacid. The London college have restrained the shops to that which grows in dry places, and is considerably the strongest, and loses of its quality if transplanted into such soils as the other naturally delights in. The roots produced in low watery grounds have a remarkably faint smell in comparison of the others, and sometimes scarce any at all. Wild valerian is a medicine of great use in nervous disorders; and is particularly serviceable in epilepsies proceeding from a debility of the nervous system. It was first brought into esteem in these cases by Fabius Columna, who by taking the powdered root in the dose of half a spoonful, was cured of an inveterate epilepsy after many other medicines had been tried in vain. Repeated experience has since confirmed its efficacy in this disorder; and the present practice lays considerable stress upon it. The common dose is from a scruple to a dram; in infusion from one to two drams. Its unpleasant flavour is most effectually concealed by a suitable addition of mace.—Cats are very fond of the smell of this root, and seem to be intoxicated by it.

VALERIUS MAXIMUS, a Latin historian, sprung from the families of the Valerii and Fabii, which made him take the name of *Valerius Maximus*. He studied polite literature, and afterwards followed Sextus Pompey to the wars. At his return he composed an account of the actions and remarkable sayings of the Romans and other great men; and dedicated that work to the emperor Tiberius. Many of the learned think that this is the same that is now extant and bears the

name of *Valerius Maximus*; but others maintain, that what we have now is only an abridgment of the work written by this celebrated historian, and that this abridgment was made by one Nepotian of Africa. However, this work is well written, and contains a great number of memorable examples and facts performed by the Greeks and Romans that are worthy of being read.

VALET, a French term, used as a common name for all domestic men-servants employed in the more servile offices, as grooms, footmen, coachmen, &c. But with us it is only used in the phrase *valet de chambre*, which is a servant whose office is to dress and undress his master, &c.

VALETUDINARY, among medical writers, denotes a person of a weak and sickly constitution, and frequently out of order.

VALGUS, *Bow* or *Bandy Legged*. Some children are bow-legged from their birth; others become so from setting them on their feet too early. The tibia of some is crooked; the knees of others are distorted; from a fault in the ankle, the feet of some are turned inwards, these are called *vargi*; and in others they turn outwards, these are called *valgi*. The best method of preventing these disorders in weakly children, is to exercise them duly, but not violently; by dancing or tossing them about in one's arms, and not setting them much on their feet, at least not without properly supporting them: if the disorder attends at the birth, or increases after it is begun, apply emollients, then apply boots of strong leather, wool, &c. as required to dispose the crooked legs gradually to a proper form; or other instruments may be used instead of boots; which, when not too costly, are usually to be preferred. Slighter instances of these disorders yield to careful nursing without instruments.

VALID, in law, an appellation given to acts, deeds, transactions, &c. which are clothed with all the formalities requisite to their being put into execution, and to their being admitted in a court of justice.

VALLADOLID, an ancient, large, and handsome city of Spain, in Old Castile, and capital of a principality of the same name, with a bishop's see and an university. It is surrounded with strong walls, embellished with handsome buildings, large public squares, piazzas, and fountains. It is large and populous, containing 11,000 houses, with fine long and broad streets, and large high houses, adorned with balconies. The market-place, called *El Campo*, is 700 paces in circumference, surrounded with a great number of convents, and is the place where the fairs are kept. There is another square in the middle of the city, surrounded with handsome brick houses, having under them piazzas, where people may walk dry in all weathers. Within these piazzas merchants and tradesmen keep their shops; all the houses are of the same height, being four stories; and there are balconies at every window, of iron gilt. In the whole there are 70 monasteries and nunneries; the finest of which is that of the Dominicans, remarkable for its church, which is one of the most magnificent in the city. The kings resided a long while at this place; and the royal palace, which still remains, is of very large extent, though but two stories high; within are fine paintings of various kinds, and at one of the corners a curious clock, made in the same

Valcs
Valladolid

Valdava
Vanbrugh.

fame manner as that of Strasburg. The house of the inquisition is an odd sort of structure, for there are no windows, but a few holes to let in the light. The environs of the city are a fine plain, covered with gardens, orchards, vineyards, meadows, and fields. It is seated on the rivers Escurva and Pefuerga, in W. Long. 4. 1. N. Lat. 41. 42.

VALSALVA (anthony Maria), an eminent physician and anatomist, was born at Imbola in 1666, and was the disciple of Malpighi. He taught anatomy at Bologna with uncommon applause, and died in 1723. He wrote an excellent treatise on the Ear, and other works in Latin, printed at Venice, in 4to.

VALUE, in commerce, denotes the price or worth of any thing.

VALUE, in music. Sounds are either comparatively high or low, long or short. In either of these cases they may be said to have a value. In the first their value is relative to harmony, in the last to rhythmus. The value of any particular sound, considered as high or low, is the degree in which it is placed with relation to any other sound above or beneath it, ascertained by comparison.

VALVE, in hydraulics, pneumatics, &c, is a kind of lid, or cover of a tube or vessel so contrived as to open one way, but which, the more forcibly it is pressed the other way, the closer it shuts the aperture; so that it either admits the entrance of a fluid into the tube or vessel, and prevents its return; or admits its escape, and prevents its re-entrance.

VALVE, in anatomy, a thin membrane applied on several cavities and vessels of the body, to afford a passage to certain humours going one way, and prevent their reflux towards the place from whence they came.

VAMPYRE, a species of bat. See VESPERTILIO.

VAN, a term derived from the French *avant*, or *avant*, signifying before or foremost of any thing; thus we say, the van-guard of the army, &c.

VANBRUGH (Sir John), a celebrated English dramatic writer and architect, was descended of a family in Cheshire which came from France, though by his name he appears to have been originally of Dutch extraction. He was born about the middle of the reign of Charles II. and received a liberal education. His first comedy, called the *Relapse*, or *Virtus in Danger*, was acted in the year 1697 with great applause; which gave him such encouragement, that he wrote 11 more comedies. He was the friend of Mr Congreve, whose genius was naturally turned for dramatic performances; and these two gave new life to the English stage, and restored its reputation, which had been some time sinking: but their making vicious persons their most amiable and striking characters, and their bordering too much on obscenity, could be of no service to the cause of virtue; and therefore it was not without reason that they were attacked by Mr Collier, in his piece on the Immorality and Profaneness of the Stage. However, either the reputation Sir John gained by his comedies, or his skill in architecture, procured him very considerable advantages. He was appointed Clarencieux king at arms, which he afterwards disposed of. In 1716 he was appointed surveyor of the works at Greenwich hospital; he was likewise made comptroller-general of his Majesty's works, and surveyor of all the gardens and waters. He was an able architect; but his per-

formances in that way are esteemed heavy. Under his direction were raised Blenheim-house in Oxfordshire, Claremont in Surry, and his own house at Whitehall. He died of a quinsy in 1726.

VANDYCK (Sir Anthony), a celebrated painter, was born at Antwerp in the year 1599. It is said that Vandyck's mother was passionately fond of embroidery, that she excelled in it, and embroidered several historical subjects with such surprising skill, that they have been esteemed masterpieces by proficient in that art. Being desirous to have her son instructed in the first rudiments of grammar, he began by sending him to school to learn reading and writing. As he had ink, paper, and pens, at command, he amused himself more with drawing figures, and other slight sketches, than with making letters. One day his master having threatened to whip one of his school-fellows, Vandyck positively assured him, that he need not fear his master's threats, as he would take care to prevent his receiving the threatened correction.—“How so?” replied his school-fellow. “I'll paint (replied Vandyck) a face on your posterior;” which he did with such skill, that when the master drew up the curtain, he laughed so immoderately, that he forgave the culprit. After giving several early proofs of his excellent genius, he became the disciple of the illustrious Rubens. In the church of the Augustines at Antwerp, at the high altar, is a celebrated picture of Rubens, representing, in one part, the Virgin Mary sitting with the child Jesus in her lap, and in another part several saints and saintesses standing. The breast of one of these, St Sebastian, is said to have been painted by Vandyck when he was only a disciple of Rubens. This great master being engaged one day abroad, his disciples went into his painting-room, where, after having been some time employed in admiring his works, they began to play or romp in such a manner, that the breast of St Sebastian, which was not yet dry, was brushed away by a hat thrown at random. This accident put an end to their play: they were very anxious to restore it, fearing that if Rubens discovered it they should all be discarded. At length it was agreed that Anthony should undertake to mend the saint's breast. In short, taking his master's pallet and brushes, he succeeded so well, that his companions imagined Rubens would overlook it. They were mistaken; for Rubens at his return knew immediately that some one had touched upon his performance: calling his disciples, he asked them why any one had dared to meddle with his painting? They were some time doubtful whether they should confess or deny the fact. Threats at length prevailed: they owned that Vandyck had thrown his hat upon it. Upon this, closeting Vandyck, instead of chiding him, he told him, that “it was proper and even necessary for him to travel into Italy, the only school that produced excellent painters; and that, if he would take his advice, he would arrive at the highest perfection.” Vandyck replied, that “he was very desirous of it; but that his purse was not equal to such a journey, and that he feared he should be obliged to sell his hat on the road.” Rubens assured him that that should be his concern; and accordingly, a few days after, he made him a present of a purse full of pistoles, and added to that gift a dapple grey horse, of great beauty, to carry him thither. In return for this, Vandyck painted his

Vandyck-

Vandyck. master a chimney-piece; and afterwards set out for Italy, about the year 1621, being then about 23 or 22 years of age. Having staid a short time at Rome, he removed to Venice, where he attained the beautiful colouring of Titian, Paul Veronese, and the Venetian school, which appeared from the many excellent pictures he drew at Genoa.

After having spent a few years abroad, he returned to Flanders, with so noble, so easy and natural a manner of painting, that Titian himself was hardly his superior; and no other master could equal him in portraits. Soon after his return, he accidentally met with D. Teniers, who accosted him with great politeness, and asked him whether he had much business since he came from Rome? "What business, think you, can I have had time to do?" (replied Vandyck), "I am only just arrived here. Would you believe, that I offered to draw that fat brewer's picture who just passed by us for two pistoles, and that the looby laughed in my face, saying it was too dear? I assure you, that if the cards do not turn up better, I shall make no long stay at Brussels." Soon after this, he painted those two famous pictures, the Nativity, and a dying Christ; the first in the parish church, the second in that of the Capuchins, at Termond.

When he was in Holland he was very desirous to see Francis Hals the painter, who had great reputation then for portraits. On entering his room, he asked to have his picture drawn. Hals, who knew Vandyck only by fame, undertook it, and went to work. The latter seeing his head finished, rose up, saying, that it was a striking likeness. Afterwards he proposed to Hals, that if he would sit in return, he would also draw his picture; to which Hals having agreed, merely from curiosity, exclaimed, on seeing his picture so soon finished, "Thou art the devil, or else Vandyck." This picture of Hals has been engraved by Colter, at the Hague.

Vandyck finding he could not make a fortune in his own country, took a resolution of going over into England. Accordingly he borrowed some guineas of Teniers, and set out, furnished with letters of recommendation. His superior genius soon brought him into great reputation; and above all, he excelled in portraits, which he drew with an inconceivable facility, and for which he charged a very high price, according to the instructions which had been given him on that head. It is affirmed, that for some of them he received 400 guineas apiece. He soon found himself loaded with honours and riches; and as he had a noble and generous heart, he made a figure suitable to his fortune. He married one of the fairest ladies of the English court, a daughter of the lord Rutliven, earl of Gowry; and, though she had but little fortune, maintained her with a grandeur answerable to her birth. He himself was generally richly dressed; his coaches and equipage were magnificent, and his retinue was numerous. His table was elegant, and plentifully furnished; and he often entertained his guests after dinner with a concert performed by the best English musicians of London. In short, his house was so frequented by persons of the greatest quality of both sexes, that his apartments rather resembled the court of a prince than the lodgings of a painter. Notwithstanding this expence, he amassed great wealth; when a chemist had

the art to insinuate himself into his esteem, and inspired him with a desire of converting copper into gold; but the secret had no other effect, than making him convert his gold into smoke. Rubens being informed of it, wrote to his disciple: he acknowledged his error, and corrected it. At length Vandyck being at an early age subject to the gout, it undermined him by degrees, and carried him to the grave in the year 1641, at the age of 42. He was buried in St Paul's; and left to his heirs a considerable estate, which some have made to amount to 40,000*l.* sterling.

VANE, a thin slip of bunting hung to the mast-head, or some other conspicuous place in the ship, to show the direction of the wind. It is commonly sewed upon a wooden frame called the *stock*, which contains two holes whereby to slip over the spindle, upon which it turns about as the wind changes.

VANILLA, or **VANILLO**. See **EPIDENDRUM**.

VAPOUR, in philosophy, the particles of bodies rarified by heat, and thus rendered specifically lighter than the atmosphere, in which they rise to a considerable height. See **EVAPORATION**, **DAMP**, **GAS**, &c.

Many kinds of vapour are unfriendly to animal life, but the most noxious are those which arise from metallic substances. In the melting and refining of lead, a white vapour arises, which, falling upon the grass in the neighbourhood, imparts a poisonous quality to it, so that the cattle which feed there will die; and in like manner stagnant waters impregnated with this vapour will kill fish. Phlogistic vapours are also extremely noxious; and hence painters, and others who are exposed to these vapours, are generally unhealthy. In some places the earth exhales vapours of a very noxious quality; such as the Grotto del Cani, and other places in Italy, where a mephitic vapour constantly hovers over the surface of the ground, proving instantly fatal to such animals as are immersed in it. But the most formidable kind of vapours are those which issue from the mouths of volcanoes, and which seem to be a combination of all others, joined to such a quantity of electric matter as to produce the greatest mischiefs. In some parts of the world there have been instances of people killed, and almost torn to pieces, by a vapour suddenly bursting out of the earth under their feet.

Of the aqueous vapour raised from the earth by the sun's heat are formed the clouds; but though these are commonly at no great height from the earth, we cannot from thence determine the height to which the vapours ascend. Indeed, considering the great propensity of water, and even quicksilver, to evaporate in the most perfect vacuum we can make, it is by no means probable that any limit can be fixed for this ascent.

VAPOURS, in medicine, a disease properly called *hype*, or the *hypochondriacal disease*; and in men particularly, the *spleen*. See **MEDICINE**, n° 385.

VARENIVS (Augustus), a famous Lutheran divine, was born in the duchy of Lunenburg in 1620. He became so well skilled in the Hebrew tongue, that he was considered in Germany as the best skilled in that language of all the Protestants, except the Buxtorfs; and he had such a prodigious memory, that he knew the Hebrew text of all the Old Testament by heart. He wrote a Commentary on the prophecy of Isaiah, and many other works.

He ought not to be confounded with *Bernard Varenivus*,

rentur, a Dutchman and an able physician, who wrote an esteemed geographical treatise, intitled *Geographia universalis, in qua Affectiones generales Telluris explicantur*, which was translated by Sir Isaac Newton.

VARI, in medicine, little, hard, and ruddy tumours, which frequently infest the faces of young persons of a hot temperament of body.

VARIATION, the angle contained between the true meridian and the magnetic meridian.

After the discovery of that most useful property of the magnet, or loadstone, namely, the giving hardened iron and steel a polarity, the compass was for many years used without knowing that its direction in any wife deviated from the poles of the world: and about the middle of the 16th century, so certain were some of its inflexibly pointing to the north, that they treated with contempt the notion of the variation, which about that time began to be suspected. However, careful observations soon discovered, that in England and its neighbourhood, the needle pointed to the eastward of the true north: but the quantity of this deviation being known, mariners became as well satisfied as if the compass had none; because they imagined that the true course could be obtained by making allowance for the true variation.

From successive observations made afterwards, it was found, that the deviation of the needle from the north was not a constant quantity, but that it gradually diminished; and at last, about the year 1660, it was found at London that the needle pointed due north, and has ever since been getting to the westward; and now the variation is more than 20° to the westward of the north: so that in any one place it may be suspected the variation has a kind of libratory motion, traversing through the north to unknown limits eastward and westward. But the settling of this point must be left to time.

During the time of the said observations it was also discovered, that the variation of the needle was different in different parts of the world, it being west in some places when it was east in others; and in places where the variation was of the same name, yet the quantity of it greatly differed. It was therefore found necessary, that mariners should every day, or as often as they had opportunity, make during their voyage proper observations for an amplitude or azimuth; whereby they might be enabled to find the variation of the compass in their present place, and thence correct their courses.

Dr Halley published in the last century a theory of the variations of the compass. In this work he supposes there are four magnetic poles in the earth; two of which are fixed and two moveable, by which he explains the different variation of the compass at different times in the same place. But it is impossible to apply exact calculations to so complicated an hypothesis. M. Euler, son of the celebrated geometrical of that name, has however shown, that two magnetic poles placed on the surface of the earth will sufficiently account for the singular figure assumed by the lines which pass through all the points of equal variation in the chart of Dr Halley.

M. Euler first examines the case wherein the two magnetic poles are diametrically opposite; second, he places them in the two opposite meridians, but at un-

equal distances from the poles of the world; third, he places them in the same meridians. Finally, he considers them situated in two different meridians. These four cases may become equally important; because, if it is determined that there are only two magnetic poles, and that these poles change their situations, it may sometime hereafter be discovered that they pass through all the different positions.

Since the needle of the compass ought always to be in the plane which passes through the place of observation and the two magnetic poles, the problem is reduced to the discovery of the angle contained between this plane and the plane of the meridian. M. Euler, after having examined the different cases, finds that they also express the earth's magnetism, represented in the chart published by Mess. Montaigne and Dodson in 1744, particularly throughout Europe and North America, if the following principles are established.

Between the arctic pole and the magnetic pole $14^{\circ} 53'$.

Between the antarctic pole and the other magnetic pole $29^{\circ} 23'$.

$53^{\circ} 18'$ the angle at the north pole, formed by the meridian's passing through the two magnetic poles.

250° the longitude of the meridian, which passes over the northern magnetic pole.

As the observations which have been collected with regard to the variation are for the most part loose and inaccurate, it is impossible to represent them all with precision; and the great variations observed in the Indian Ocean seem to require, says M. Euler, that the three first quantities should be 14, 35, and 65 degrees. In the mean time, the general agreement is sufficiently satisfactory.

The high reputation of Dr Halley's magnetical chart renders it more particularly necessary to point out the errors contained therein. There is evidently too little distance between the lines of no variation, of which one crosses the equator 17° westward of London, and the other 119° to the eastward. This makes 136° only; whereas it should necessarily exceed 180, and even 200, inasmuch as the pole of the world is supposed further distant from the magnetic pole towards the south than in the north, as is required by the other phenomena. Again, upon the coasts discovered by Diemen, there was no variation in 1642; and Dr Halley also supposes there was none in 1700. Meanwhile, by the alteration observed at Paris, the line of no variation should be advanced 60° towards the south, which will agree better with the calculations, and prove that the distance of the two intersections was really greater than Dr Halley had established.

The table of variation of Mess. Montaigne and Dodson is accompanied with several intertelling particulars, which equally deserve to be inserted here.

At Barbadoes (says Captain Snow), the variation seems very nearly at a stand: for in the road I observed 5° east; and by Dr Halley's draught, in the year 1701, $5\frac{1}{2}^{\circ}$. In 1747, at Port Royal keys, Jamaica, I observed the variation $7^{\circ} 20' E.$; and on the coast of Carthage, the same week, off the high land of Santa Martha, $7^{\circ} 45'$ nearly south of Port Royal. Therefore these curves are not much altered: the curve at Jamaica is nearly at a stand, as though tied, and the fourth part of them with the rest dropping to the westward.

Variation
||
Variety.

Under the equator, in longitude 40° E. of London, the highest variation during the whole 56 years appears to be $17^{\circ}\frac{1}{2}$ W. and the least $16^{\circ}\frac{1}{2}$ W.: and in latitude 15° N. longitude 60° W. from London, the variation has been constantly 5° E. But in other places the case has been widely different. For in the latitude of 10° S. longitude 60° E. from London, the variation has decreased from 17° W. to $7^{\circ}\frac{1}{2}$ W.; and in latitude 10° S. longitude 5° W. from London, from $20^{\circ}\frac{1}{2}$ W. to $12^{\circ}\frac{1}{2}$ W.; and in latitude 15° N. longitude 20° , it has increased from 1° W. to 9° W.

But there is still a more extraordinary appearance in the Indian sea. For instance, under the equator:

| LONGITUDE MAGNETICAL VARIATION | | |
|--------------------------------|-----------------------|-----------------------|
| E. from London. | in 1700. | in 1756. |
| Degrees. | Degrees. | Degrees. |
| 40 ——— | $16\frac{1}{2}$ West. | $16\frac{1}{2}$ West. |
| 45 ——— | $17\frac{1}{2}$ W. | $14\frac{1}{2}$ W. |
| 50 ——— | $17\frac{1}{2}$ W. | $11\frac{1}{2}$ W. |
| 55 ——— | $16\frac{1}{2}$ W. | $8\frac{1}{2}$ W. |
| 60 ——— | $15\frac{1}{2}$ W. | 6 W. |
| 65 ——— | $13\frac{1}{2}$ W. | $4\frac{1}{2}$ W. |
| 70 ——— | $11\frac{1}{2}$ W. | $3\frac{1}{2}$ W. |
| 75 ——— | $9\frac{1}{2}$ W. | 1 W. |
| 80 ——— | $7\frac{1}{2}$ W. | $0\frac{1}{2}$ East. |
| 85 ——— | $5\frac{1}{2}$ W. | $1\frac{1}{2}$ E. |
| 90 ——— | $4\frac{1}{2}$ W. | 1 E. |
| 95 ——— | $3\frac{1}{2}$ W. | $0\frac{1}{2}$ West. |
| 100 ——— | $2\frac{1}{2}$ W. | 1 W. |

Where the west variation, in the longitude 40° E. is the same in both the above years; and in 1700 the west variation seemed to be regularly decreasing from longitude 50° E. to the longitude 100° E.: but in 1756, we find the west variation decreasing so fast, that we have east variation in the longitude 80° , 85° , and 90° E. and yet in the longitude 95° and 100° E. we have west variation again.

To these remarks may be subjoined the following extracts from the *Exposition du calcul astronomique*, by M. de la Lande.

“ At the royal observatory in Paris, a magnetical needle of four inches deviated from the N. $18^{\circ} 10'$ towards the west, on the 15th of February 1759: and on the 22d of April 1760, the same needle varied $18^{\circ} 20'$. It is indeed natural to conceive, that nothing can be precisely ascertained by $10'$ upon a circle whose diameter is only four inches. It is nevertheless sufficiently evident, that this variation continues to increase at Paris. In 1610 the needle declined 8° towards the east, so that the variation has changed $26^{\circ} 20'$ in the space of 150 years; and this appears particularly since 1740: for the same needle, which has always been used by M. Maraldi, is more than 3° advanced towards the west, beyond what it was at that period; and this makes $9'$ in one year.”

VARIETY, a change, succession, or difference, in the appearance or nature of things; in opposition to uniformity. See UNIFORMITY and Variety.

VARIETY, in botany, a plant changed by some accidental cause, which being removed, the variety or mutation disappears, and the species is restored. As many plants of different form and appearance as are produced from seed of the same species, are to be regarded as genuine varieties, and in all cases to be distinguished with great accuracy from the species.

In the form and disposition of the parts of each individual of the same species, there exists, in general, a constant uniformity. Different causes, however, as culture, climate, exposure, age, diseases, luxuriance or poverty of nourishment, contusions, and other circumstances, produce monstrous appearances and accidental varieties in the parts of plants.

It is known, that a superabundance of nourishment gives rise to the numerous tribe of double and prolific flowers: the same cause gives to all the parts of the plant a thickness and extent by no means natural to them. Hence, likewise, the prodigious multiplication of the leaves of some plants, which increase to such a degree, as frequently to injure the flower and fruit.

The leaves of young trees and of new shoots are much larger, and less cut and ramified, than those of a grown tree of the same species. In holly, the leaves lose their prickles when the tree waxes old.

The lower leaves of aquatic plants, as cress-foot and water-drop-wort, are frequently finely cut like hairs, whilst those above are of a different form. Plants of the same species that grow in another soil have no diversity in the form of their upper and under leaves.

Again, in mountainous plants, the lower leaves are generally more entire; the upper ones more divided. Burnet, laxifrage, anise, and coriander, furnish examples.

The seeds or grains of many grasses, particularly of rye, are sometimes prolonged into a horny appearance of a fungous substance, that is pretty hard, and as it were cartilaginous. Some of these monstrous productions are more than two inches long. Rye diseased in this manner, is frequently attended with fatal consequences to such as eat of the bread prepared from it. The same appearance has been observed in *gramen aquaticum fluitans*, and carex. This disease, termed by Linnaeus *clavus*, is common in moist years and rainy seasons, and seems to be principally owing to a defect of perspiration.

The flowers and seeds of many of the esculent grasses, and some other plants, are frequently reduced into a black powder. This appearance has been particularly observed in wheat, rye, barley, oats, pericaria, mariscorzonera, goats-beard, foxtail, and some of the lychnis, pink, and chick-weed tribe. In the greater number, the disease, when it attacks the flower, begins by the receptacle under the form of small black points, which insensibly reach the other parts of the flower; as the flower-cup, petals, and stamina, without attacking the pistil or female organ, which however commonly proves abortive.

The disease termed *ustilago*, or burning, differs from that just mentioned, in that it is contagious and hereditary; the seeds being the only parts that are affected by it. It has been discovered in the same species of grasses as the former, but more abundantly on Indian millet. M. Aymen, a French academician, attributes both these diseases to an internal fault in the sap.

The upper surface of the leaves of some plants, particularly of hop, melon, dead-nettle, hedge-nettle, maple, and gromwell, is subject to be covered with a white appearance, which makes the leaves seem thicker, more weighty, and more opaque. Plants which are attacked by this disease, termed by botanists *erysiphe*, rarely produce any fruit; or if they do, it is badly formed.

Variety.

Variety. formed, and has a crude disagreeable taste.

On the under surface of the leaves of ladies mantle, and a species of euphorbia with cypress leaves, is occasionally dispersed a yellowish dust, which, from its resemblance to rusty iron, has occasioned the name of *rustigo*, or *rust*, to be given to this particular disease; which, like the former, appears to proceed from a defect of perspiration.

White spots are frequently observed on some leaves, which thence appear empty, and as it were transparent: it is occasioned by the influence of a burning sun acting upon them when very much moistened, either in consequence of continued rain or a strong dew. When all the leaves are attacked with this disease, which has obtained the name of *candor*, that is, "the whites," the plant commonly perishes a few days after.

Certain plants of warm climates are subject to lose their petals when cultivated in cold countries; and that even when the fruit arrives at maturity.

Plants which grow in the shade, or in places that are deprived of a proper current of air, are apt to become meagre, and, without taking the consilience which is suitable, to perish before they have produced any fruit. Experiments demonstrate, that the feebleness of such plants proceeds less from a defect of heat, than from a privation of light.

Other causes alter the colour of leaves, and occasionally produce the beautifully variegated leaves so much in request among gardeners. Some leaves are subject to assume a deep red; this is particularly the case with herb Robert, a species of crane's bill.

The branches of ash and willow are frequently flattened in several irregular ways. This is supposed to be in consequence of two buds being naturally grafted in each other before the unfolding of the branch. Two leaves, two fruits, engrafted in this manner, produce other monstrous appearances. By means of artificial grafting, we may in like manner vary the form of leaves, stems, flowers, and fruit.

Lastly, certain insects depositing their eggs under the bark of the leaves and stems of several plants, occasion an extravasation of the sap; and hence give birth to certain singular productions, which in different bodies resemble either nuts, mushrooms, or sponges; and are either round or long, hard or soft, covered with leaves, or guarded with bristly threads.

Such are the galls of oak, which enter into the composition of ink; those of elm, lime, cistus, ground-ivy, a species of hawk-weed, the aspen-tree, and several species of willow. Those of a species of sage, called *fulcia laccifera*, are sold in the markets of the Levant by the name of *sage-apples*. Tournefort relates that they are round, nine or ten lines in diameter; of the colour of ashes, cottony, with a white pulp that is somewhat transparent, sweet, and of a very agreeable taste. Those of the scarlet-oak are two lines in diameter; the substance is very red, and being dried, is the kermes, or scarlet-paleil, so well known by the dyers.

Of the same nature with the galls just mentioned, are those strange bodies covered with green, red, or yellow fibres, termed *bedeguar*, which a fly of the same kind produces upon the wild rose: such are likewise the small bladders on the surface of the elm-leaves, which are filled with gnats, and with an alluring balmy liquor that is an excellent vulnerary.

Such are the principal accidents to which the parts of plants are subject, and which give rise to the numerous tribes of varieties in the vegetable kingdom.

VARIOLA, the SMALL-POX. See MEDICINE, n° 326—328.

VARIX, in medicine, the dilatation of a vein, arising from the too great abundance or thickness of the blood. See SURGERY, n° 14, *et seq.*

VARNISH, a thick, viscid, shining liquor, used by painters, gilders, and various other artificers, to give a gloss and lustre to their works; as also to defend them from the weather, dust, &c.

There are several kinds of varnishes in use, and many receipts have been published for the preparation of them; but very few of these can be depended on. The following are extracted from Dr Lewis's Commerce of Arts, and seem to be well authenticated.

1. *Gold-coloured Varnish, or Lacquer*.—Silver, coated with a transparent gold-coloured varnish, is made to resemble gold so exactly, as wholly to supply the place of gold in some of the works called *gilt*. The basis of the varnish, or what gives adhesiveness and glossiness to the colouring matter, is a solution of lac made in spirit of wine.

Stick-lac is only to be used for varnishes: what is called *shell-lac*, or the grains formed into plates by melting them in boiling water, does not answer so well. The spirit must be highly rectified, or freed as much as possible from any admixture of phlegm or water *. * See Dissolution, n° 6. Some seed-lac, reduced into fine powder, is then added to it, in the proportion of about three ounces to a pint: the vessel being set in a moderate warmth for 24 hours and frequently shaken, a part of the lac dissolves; and the spirit, now tinged of a reddish brown colour, is strained off from the undissolved part, and set by for a day or two to settle. The digestion should be performed in a wide-mouthed vessel, covered so as to prevent the exhalation of the spirit: the undissolved lac softens into a viscous mass, so as scarce to be got out through a narrow aperture.

In different portions of the foregoing solution, poured off clear after the straining and settling, some gamboge and annatto are dissolved separately; the gamboge communicates a high yellow colour, and the annatto a deep reddish yellow. The solution of the gamboge is mixed with about half its quantity of that of the annatto, and trial made of the mixture on some silver leaf: if the colour inclines too much to the yellow or the red, more of the one or the other liquor is added till the true golden colour is obtained. There are sundry other materials, from a due mixture of which a like colour may be produced; such as turmeric, saffron, dragon's-blood, &c.

The silver leaf being fixed on the subject, in the same manner as gold leaf, by the interposition of proper glutinous matters, the varnish is spread upon the piece with a brush or pencil. The first coat being dry, the piece is again and again washed over with the varnish till the colour appears sufficiently deep. What is called *gilt leather*, and many picture-frames, have no other than this counterfeit gilding. Washing them with a little rectified spirit of wine affords a proof of this; the spirit dissolving the varnish, and leaving the silver leaf of its own whiteness. For plain frames, thick tin-leaf may be used instead of silver. The tin-leaf, fixed on the

Variola
H
Varnish.

Varnish.

the piece with glue, is to be burnished, then polished with emery and a fine linen cloth, and afterwards with putty applied in the same manner: being then lacquered over with the varnish five or six times, it looks very nearly like burnished gold. The same varnish, made with a less proportion of the colouring materials, is applied also on works of brass; both for heightening the colour of the metal to a resemblance with that of gold, and for preserving it from being tarnished or corroded by the air.

2. *Spirit Varnish*. Black varnish, for japanning on wood or leather, is prepared by mixing lamp-black or ivory-black with a proper quantity of a strong solution of gum lac in spirit of wine, such as that above-described. The lamp-black is commonly preferred to the ivory-black, on account of its uniting better with the fluid, and working smoother. The thicker part of the varnish, which settles at the bottom, is used with the lamp-black for the first coatings, and the mixture applied at different times, in a hot room, one layer after another is dry, till a full body of colour is obtained: after which the piece is washed over in the same manner, several times, with the finer part of the varnish, just tinged with the black, so as to make a coating of sufficient thickness to bear polishing with tripoli.

3. *Amber Varnishes for Papier Maché, &c.* Papier maché is made of cuttings of white or brown paper, boiled in water, and beaten in a mortar, till they are reduced into a kind of paste; and then boiled with solution of gum-arabic or of size, to give tenacity to the paste, which is afterwards formed into different toys, &c. by pressing it into oiled moulds. When dry, it is done over with a mixture of size and lamp-black, and afterwards varnished. The black varnish for these toys is prepared as follows. Some colophony, or turpentine boiled down till it becomes black and friable, is melted in a glazed earthen vessel, and thrice as much amber in fine powder sprinkled in by degrees, with the addition of a little spirit or oil of turpentine now and then: when the amber is melted, sprinkle in the same quantity of sarcocolla, continuing to stir them, and to add more spirit of turpentine, till the whole becomes fluid; then strain out the clear through a coarse hair-bag, pressing it gently between hot boards. This varnish, mixed with ivory-black in fine powder, is applied, in a hot room, on the dried paper paste; which is then set in a gently heated oven, next day in a hotter oven, and the third day in a very hot one, and let stand each time till the oven is grown cold. The paste thus varnished is hard, durable, glossy, and bears liquors hot or cold.

A more simple amber-varnish, of great use for many purposes, and said to be the basis of the finer varnishes which we see on coaches, &c. is prepared, by gently melting the amber in a crucible till it becomes black; then reducing it into a powder, which looks brown; and boiling the powder in linseed oil, or in a mixture of linseed oil and oil of turpentine. Drying oil is commonly made choice of by the workmen; but it seems more eligible here to take the oil unprepared, that the boiling requisite for giving it the drying quality may be employed at the same time in making it act upon the amber.

By the previous melting of the amber, its nature is

changed, and part of its oily and saline matter expelled, as happens in the common distillation of it. When the distillation is not far protracted, the caput mortuum, or shining black mass which remains in the retort, answers as well as the amber melted on purpose. Hence some of our chemists, instead of urging the distillation to the utmost, by which the amber would be reduced to a mere coal, find it more advantageous to discontinue the process when the thinner oil and greater part of the salt have arisen, that the remaining mass may be in great measure soluble in oils, so as to supply the common demand of the varnish-makers.

It has generally been thought, that amber will not at all dissolve in oils till it has thus suffered a degree of decomposition by fire. Hoffmann relates an experiment in his *Observations Physico-chemicae*, which discovers the solubility of this concrete in its natural state. Powdered amber, with twice its quantity of oil-olive, was put in a wide-mouthed glass, and a digester, or strong copper vessel, being filled about one-third with water, the glass was placed in it, the cover of the digester screwed down tight, and a moderate fire continued an hour or more: when cold, the amber was found dissolved into a gelatinous transparent mass.

In Dr Stockar's very curious *Specimen inaugurale de succino*, printed at Leyden in 1760, there are sundry more important experiments on this subject, made by himself and Mr Ziegler of Winterthur. They found, that by continuing a simmering heat 12 hours, and confining the vapour as much as stone-ware vessels would bear without bursting (the danger of which was avoided by making a small notch in the cork-stoppers) powdered amber dissolved perfectly in expressed oils, in turpentine, and in balsam of copaiba: a strong copper vessel, with a cover screwed on it, seems most eligible, and for the greater security, a valve may be made in the cover, kept down by a spring that shall give way before the confined vapour is of sufficient force to be in any danger of bursting the vessel. Though such a heat as converts part of the oil into strong elastic vapours, and the forcible compressure of the vapour, are expedient for hastening the dissolution, they do not appear to be essentially necessary; for by digestion for a week in close-stopped glass-vessels, in which the compressure could not be very great, solutions equally perfect were obtained.

The solution in rape-seed oil, and in oil of almonds, was of a fine yellowish colour; in linseed-oil, gold-coloured; in oil of poppy-seeds, yellowish red; in oil olive, of a beautiful red; in oil of nuts, deeper coloured; and in oil of bays, of a purple red. It is observable that this last oil, which of itself, in the greatest common heat of the atmosphere, proves of a thick butyraceous consistence, continued fluid when the amber was dissolved in it. The solutions made with turpentine, and with balsam of copaiba, were of a deep red colour, and on cooling hardened into a brittle mass of the same colour. All the solutions mingled perfectly with spirit of turpentine. Those made with the oils of linseed, bays, poppy-seeds, and nuts, and with balsam of copaiba and turpentine, being diluted with four times their quantity of spirit of turpentine, formed hard, tenacious, glossy varnishes, which dried sufficiently quick, and appeared greatly preferable to those made in the common manner from melted amber.

Varnish.

See Gilding, n^o 5.

4. *Varnish for Metals.* Iron snuff boxes, mourning-buckles, &c. are coloured black, by making them considerably hot, and applying on them in this state a thick mixture of lamp black, with a certain varnish called *gold size*. There is a *gold size* used for gilding, or fixing gold leaf on wood, &c. † The size here meant is a composition of a different kind, consisting of drying oil, turpentine, and the pigment called *Naples yellow*; which last ingredient is used for giving a high gold colour to the mixture, to fit it for some of the other purposes for which it is employed.

The workmen are still frequently to employ for this purpose a mixture of lamp-black with the scummings, &c. of different oil-paints: the mixture is applied with a pencil, and the piece afterwards baked in an oven, with a heat somewhat greater than that used for the papier mache. Naples yellow, a superfluous ingredient in the black varnish, is the basis of the dark brown which we see on some iron snuff-boxes, this pigment changing to a brown in baking with the varnish.

Laying on of VARNISHES. 1. If you varnish wood, let your wood be very smooth, close-grained, free from grease, and rubbed with rushes. 2. Lay on your colours as smooth as possible; and if the varnish has any blisters in it, take them off by a polish with rushes. 3. While you are varnishing, keep your work warm, but not too hot. 4. In laying on your varnish, begin in the middle, and stroke the brush to the outside; then to another extreme part, and so on till all be covered; for if you begin at the edges, the brush will leave blots there, and make the work unequal. 5. In fine works, use the finest tripoli in polishing: do not polish it at one time only; but after the first time, let it dry for two or three days, and polish it again for the last time. 6. In the first polishing you must use a good deal of tripoli, but in the next a very little will serve: when you have done, wash off your tripoli with a sponge and water: dry the varnish with a dry linen-rag; and clear the work, if a white ground, with oil and whiting; or if black, with oil and lamp-black.

VARNISH also signifies a sort of shining coat, where-with potter's ware, delft-ware, china-ware, &c. are covered, which gives them a smoothness and lustre. Melted lead is generally used for the first, and smalt for the second. See GLAZING.

VARNISH, among medalists, signifies the colours antique medals have acquired in the earth.

The beauty which nature alone is able to give to metals, and art has never yet attained to counterfeit, enhances the value of them: that is, the colour which certain soils in which they have a long time lain tinges the metals withal; some of which are blue, almost as beautiful as the turquoise; others with an inimitable vermilion-colour; others with a certain shining polished brown, vastly finer than Brasil figures.

The most usual varnish is a beautiful green, which hangs to the finest strokes without effacing them, more accurately than the finest enamel does on metals.

No metal but brass is susceptible of this; for the green rust that gathers on silver always spoils it, and it must be got off with vinegar or lemon juice.

Falsifiers of medals have a false or modern varnish, which they use on their counterfeits, to give them the appearance or air of being antique. But this may be discovered by its softness; it being softer than the

natural varnish, which is as hard as the metal itself.

Some deposit their spurious metals in the earth for a considerable time, by which means they contract a sort of varnish, which may impose upon the less knowing; others use sal armoniac, and others burnt paper.

VARRO (MARCUS TERENTIUS), the most learned of all the Romans, was born 28 B. C. He was a senator of the first distinction, both for birth and merit; and bore many great offices. He was an intimate friend of Cicero; and this friendship was confirmed and immortalized by a mutual dedication of their learned works to each other. Thus Cicero dedicated his *Academic Questions* to Varro; and Varro dedicated his treatise on the Latin tongue to Cicero. In the civil wars he was zealously attached to Pompey; but after his defeat soon submitted to Cæsar, who was reconciled to him. From thence he applied his whole time to letters, and had the charge of the Greek and Latin libraries at Rome. He was above 70 when Antony proscribed him; however, he found means to escape and save his life, though he could not save some of his works and his library from being plundered by the soldiers. After this storm was over, he pursued his studies as usual; and Pliny relates, that he continued to study and to write when he was 88 years of age. He was 80 when he wrote his three books *De re Rustica*, which are still extant. Five of his books *De lingua Latina*, which he addressed to Cicero, are also extant. There remain, too, divers fragments of his works, particularly of his Menippean Satires, which are medleys of prose and verse; and Scaliger has collected some of his epigrams from among the *Catalecta Virgilii*. His books *De lingua Latina*, and *De re Rustica*, were printed with the notes of Joseph Scaliger, Turnebus, and Victorius, by Henry Stephens at Paris, 1573, in 8vo, and have been published separately since among the *Auctores de lingua Latina*, and the *Auctores de re Rustica*.

There was another Varro of antiquity, called *Atacinus*, who was born about ten years after the first, at a small town near Narbonne. Though infinitely below the Roman in learning, he was at least as good, if not a better, poet; which perhaps has made Lilius Gyraldus and other critics confound them. He composed many works in verse; some fragments of which were collected, and published with those of other ancient poets, at Lyons in 1603. His chief works were, *A poem on the war with the Sequani*, a people of Gaul; and the *Astronomics*, that went under the name of Planciades the grammarian. But the *Argonautica*, in four books, was what gained him the greatest reputation: and though indeed nothing but a translation of Apollonius Rhodius, yet was so well done, as to be commended by Quintilian.

VASCULAR, something consisting of divers vessels, as arteries, veins, &c.

VASE, a term frequently used for ancient vessels dug from under ground, or otherwise found, and preserved in the cabinets of the curious. In architecture, the appellation *vase* is also given to those ornaments placed on corniches, foehles, or pedestals, representing the vessels of the ancients, particularly those used in sacrifice, as incense-pots, flower-pots, &c.

VASSAL, in our ancient customs, signified a tenant or feudatory; or person who vowed fidelity and homage

Varro
Vassal.

Vedicam
||
Vedam.

homage to a lord, on account of some land, &c. held of him in fee; also a slave or servant, and especially a domestic of a prince. *Vassallus* is said to be *quasi inferior socius*; as the vassal is inferior to his master, and must serve him; and yet he is in a manner his companion, because each of them is obliged to the other. See *FEDAL System*.

VATICAN, a magnificent palace of the pope, in Rome, which is said to consist of several thousand rooms: but the parts of it most admired are the grand stair-case, the pope's apartment, and especially the library, which is one of the richest in the world, both in printed books and manuscripts.

VAUBAN (Sebastien le Prestre, seigneur de), marshal of France, and the greatest engineer that country ever produced, was born in 1633. He displayed his knowledge of fortification in the course of many sieges, and his services were rewarded with the first military honours. He was made governor of Lille in 1668, commissary-general of the fortifications of France in 1678, governor of the maritime parts of Flanders in 1689, and a marshal of France in 1703. He died in 1707, after having brought the arts of attacking and defending fortified places to a degree of perfection unknown before. His writings on these subjects are in the highest esteem.

VAULT, in architecture, an arched roof, so contrived that the stones which form it sustain each other.

Vaults are on many occasions to be preferred to soffits or flat ceilings, as they give a greater height and elevation, and are besides more firm and durable.

VAYER. See *MOTHE*.

UBES (St.), a sea-port town of Portugal, in the province of Estremadura, seated on a bay of the Atlantic Ocean, 21 miles south of Lisbon. It stands on an eminence, with a very strong castle built on a rock. The soil about it is fertile in corn, wine, and fruits; and it is furnished with good fish from the sea, and a small lake in the neighbourhood. Here they make great quantities of fine salt, which is carried to the American plantations. E. Long. 9. 30. N. Lat. 38. 36.

UBIQUITARIANS, in church-history, a sect of heretics who sprung up in Germany about the year 1590, and maintained that the body of Christ is *ubique*, "everywhere," or in every place, at the same time. However, they were not quite agreed among themselves; some holding that the body of Jesus Christ, even during his mortal life, was every where; and others dating the ubiquity of his body from the time of his ascension only.

UBIQUITY, OMNIPRESENCE; an attribute of the Deity, whereby he is always intimately present to all things; gives the *esse* to all things; knows, preserves, and does all in all things.

UDDER, in comparative anatomy, that part in brutes wherein the milk is prepared, answering to the mammae, or breasts, in women. See *COMPARATIVE Anatomy*, n° 42.

VEDAM, among the Indian Bramins or Brachmans, is the book of their law, containing all that they are to believe and practise. See *BRACHMANS*.

The vedam is written in what they call the *Samsortan tongue*, which is understood by such of the Bramins as never traffic. It is divided into four parts; namely, 1st, *Rogo-Vedam*, which treats of the first cause, of

the first matter, of the angels, of the soul, of rewards and punishments, of the generation and corruption of creatures, of sin, and in what manner it may be re-mitted, &c. 2d, *Iffoure-Vedam*, which treats of the powers that prelide over and govern all things. 3d, *Sama-Vedam*, containing a system of morality. And, 4th, *Addaravana-Vedam*, which treated of the religious ceremonies, temples, sacrifices, and feasts: but this last part has been lost for many years; and to this the Bramins impute the diminution of their honours, and the powers they formerly enjoyed. This book is of indisputable authority among them: but as they used frequently to dispute about interpreting it, the sense of it has been fixed by the jastiras or declarations.

VEDETTE, in war, a sentinel on horseback, with his horse's head towards the place whence any danger is to be feared, and his carbine advanced, with the butt-end against his right thigh. When the enemy has encamped, there are vedettes posted at all the avenues, and on all the rising grounds, to watch for its security.

The vedettes to the out-posts should always be double, for the following reasons: First, that whenever they make any discovery, one may be detached to the commanding officer of the out-posts; secondly, that they may keep each other watchful; and thirdly, that the vigilance of both may render it impossible for any thing to come near them without being seen. They should be at no greater distance from their detachment than 80 or 100 paces.

To VEER and HAUL, to pull a rope tight, by drawing it in and slackening it alternately, till the body to which it is applied acquires an additional motion, like the increased vibrations of a pendulum, so that the rope is straitened to a greater tension with more facility and dispatch. This method is particularly used in hauling the bowlines.

The wind is said to veer and haul when it alters its direction, and becomes more or less fair. Thus it is said to veer ast and to haul forward.

VEER, *Ter-Veer*, anciently *Camp-Veer*, a town of Zealand in the United Provinces, standing at the mouth of the East Schelde, about four miles from Middleburgh, and eight from Flushing. Veer, in Dutch, signifies a passage or ferry over an arm of the sea or a river; and as there was once a ferry here over the Schelde to the village of Compen, on the island of North Beveland, the town thereby got the name of *Veer*, *Camp-Veer*, and *Ter-Veer*. It is well fortified, and enjoys a good trade, especially to Scotland; the natives of which enjoy particular privileges here. The harbour is very good, and the arsenal the best furnished in the world. The Calvinists alone are allowed the public exercise of their religion in this town. Hence the Veres, anciently earls of Oxford, are said to have derived both their origin and name.

VEERING, the operation by which a ship, in changing her course from one board to the other, turns her stern to windward. Hence it is used in opposition to *TACKING*, wherein the head is turned to the wind and the stern to leeward.

Thus a ship, having made the necessary dispositions to veer, bears away gradually before the wind, till it blows obliquely upon the opposite side, which was formerly to leeward; and as the stern necessarily yields to this impression of the wind, assisted by the force of the helm,

Veetie
||
Veering.

Veering,
Vegs.

helm, and the action of the waves upon the same quarter, the tide which was formerly to leeward soon becomes to windward.

Since by this movement a ship loses ground considerably more than by tacking, it is rarely practised except in cases of necessity or delay: as when the violence of the wind and sea renders tacking impracticable; or when her course is slackened to wait for a pilot, or some other ship in company, &c.

It has been observed in the article TACKLING, that the change of motion in any body will be in proportion to the moving force impressed, and made according to the right-line in which that force operates. Hence it is evident, that veering as well as tacking is a necessary consequence of the same invariable principle; for as in the latter, almost the whole force of the wind and of the helm are exerted on the hind-part of the ship, to turn the prow to windward; so in the former, the same impression, assisted by the efforts of the helm, falls upon the prow to push it to leeward; and the motion communicated to the ship must in both cases necessarily conspire with the action of the wind.

Thus, when it becomes necessary to veer the ship, the sails towards the stern are either furled or brailled up, and made to shiver in the wind; whilst those near the head are spread abroad, so as to collect the whole current of air which their surfaces can contain. Hence, while the whole force of the wind is exerted on the fore-part of the ship to turn her about, its effect is considerably diminished, or altogether destroyed, on the surfaces of the after-sails. The fore-part accordingly yields to the above impulse, and is put in motion; and this movement, conspiring with that of the wind, pushes the ship about as much as is necessary to produce the effect required. When she is turned so that the wind will act upon that quarter which was formerly to leeward, her circular motion will be accelerated by extending some of the sails near the stern, as the mizen, and by placing those at the prow more obliquely, which will wheel the vessel round with her bow to the windward; in the same situation, with regard to the wind, as when close-hauled or tacking.

When the tempest is so violent as to prevent the use of sails, the effort of the wind operates almost equally on the opposite ends of the ship, so that the masts and yards situated at the head and stern counterbalance each other. The effect of the helm is also considerably diminished, because the head-way, which gives life and vigour to all its operations, is at this time feeble and ineffectual. Hence it is necessary to destroy this equilibrium which subsists between the mast and yards afore and abaft, and to throw the balance forward, in order to prepare for veering. This is accordingly performed by bracing the foremoft yards across the direction of the wind, and arranging those on the main-mast and mizen-mast directly in the line of the wind. If this expedient proves unsuccessful, and it is absolutely necessary to veer in order to save the ship from destruction, by oversetting or running ashore, the mizen-mast must instantly be cut away, and even the main-mast, if she yet remains incapable of answering the helm by bearing away before the wind.

VEGA (Lopez de), a celebrated Spanish poet, also called *Lope Felix de Vega Carpio*, was born at Madrid in 1562; and became secretary to the bishop of Avila,

Vol. X

and afterwards to the count of Lemos, the duke of Alva, &c. At length having embraced the ecclesiastical state, he received priests orders, and became knight of Malta. He died in 1635. He wrote in Spanish a great number of theatrical pieces and poems that are admired.

VEGETATION, in physiology, the act whereby plants receive nourishment and grow. See PLANT.

The process of nature in the vegetation of plants is very accurately delivered by the excellent Malpighi, to the effect following: The egg or seed of the plant being excluded out of the ovary, called *pod* or *hulk*, and requiring further fostering and brooding, is committed to the earth; which having received it into her fertile bosom, not only does the office of incubation by her own warm vapours and exhalation, joined with the heat of the sun, but by degrees supplies what the seed requires for its further growth; as abounding every where with canals and sinuses, wherein the dew and rain-water, impregnated with fertile salts, glide, like the chyle and blood in the arteries, &c. of animals. This moisture meeting with a new-deposited seed, is percolated, or strained through the pores or pipes of the outer rind or hulk, corresponding to the secundines of the fœtuses, on the inside whereof lies one or more, commonly two, thick femal leaves, answering to the placenta in women, and the cotyledons in brutes.

These feed-leaves consist of a great number of little vesiculæ, or bladders, with a tube corresponding to the navel-string in animals. In these vesiculæ is received the moisture of the earth, strained through the rind of the seed; which makes a slight fermentation with the proper juice before contained therein. This fermented liquor is conveyed by the umbilical vessel to the trunk of the little plant; and to the germ or bud, which is contiguous thereto: upon which a vegetation and increase of the parts succeed.

Such is the procedure in the vegetation of plants; which the illustrious author exemplifies in a grain of wheat, as follows: The first day the grain is sown it grows a little turgid; and the secundine, or hulk, gapes a little in several places: and the body of the plant, being continued by the umbilical vessel to a conglobated leaf (which is called the *pulp* or *stess* of the seed, and is what constitutes the flower) swells; by which means, not only the germ or sprout (which is to be the future stem) opens, and waxes green, but the roots begin to bunch out; whence the placenta, or feed-leaf, becoming loose, gapes. The second day, the secundine, or hulk, being broke through, the stem, or top of the future straw, appears on the outside thereof, and grows upwards by degrees: in the mean time the feed-leaf guarding the roots, becomes turgid with its vesiculæ, and puts forth a white down. And the leaf being pulled away, you see the roots of the plant bare; the future buds, leaves, and rest of the stalk, lying hid. Between the roots and the ascending stem the trunk of the plant is knit by the navel knot to the flower-leaf, which is very moist, though it still retains its white colour and its natural taste. The third day, the pulp of the conglobated, or round leaf, becomes turgid with the juice which it received from the earth fermenting with its own.

Thus the plant increasing in bigness, and its bud or stem becoming taller, from whitish turns greenish; the

Vegetation. lateral roots also break forth greenish and pyramidal from the gaping sheath, which adheres chiefly to the plant; and the lower root grows longer and hairy, with many fibres shooting out of the same.

Indeed there are hairy fibres hanging all along on all the roots, except on their tips; and these fibres are seen to wind about the saline particles of the soil, little lumps of earth, &c. like ivy; whence they grow curled. Above the lateral roots there now break out two other little ones.

The fourth day, the stem mounting upwards, makes a right angle with the feminal leaf: the salt roots put forth more; and the other three growing larger, are clothed with more hairs, which strictly embrace the lumps of earth; and where they meet with any vacuity, unite into a kind of net-work.

From this time forward the root pulses with more regularity downward, and the stalk upward, than before. There is, however, this great difference in their growth, that the stalk and branches find no resistance to their shooting up, while the roots find a great deal to their shooting downward by means of the solidity of the earth, whence the branches advance much faster and farther in their growth than the roots; and these last often finding the resistance of a tough earth unformountable, turn their course, and shoot almost horizontally.

As to the manner in which vegetation is effected, very little can be said. That heat, air, and light are necessary for this purpose, is known to every one; but in what manner they act, seems to be totally undiscoverable by us. The lowest degree of vegetation seems to be that of the crystallization of salts. This indeed has scarce been allowed really to be a vegetation, tho' it certainly is owing to the same causes. Whether crystallization will succeed *in vacuo*, indeed, has not been determined; but it certainly may go on without light, and in much lower degrees of heat than those in which any vegetable will grow. Light indeed seems not absolutely necessary to vegetation; for the roots of all plants grow below ground, where they are very much deprived of light. This element seems only necessary for giving a green colour to the upper part of vegetables, and perhaps strengthening them, so that they can better bear the inclemency and changes of the weather. But whatever may be the differences between the powers which produce vegetation and those of crystallization, water is the medium by which only both can act; for if a salt is perfectly dry, it will not crystallize, more than a seed will grow in dry sand or dust. Some kinds of crystallization indeed resemble vegetation so much, that we can scarce avoid ascribing them to the same cause. Of these the most remarkable is the arbor Dianæ, or compound of nitrous acid and silver †. Several curious crystallizations, or vegetations as they are called, may also be formed with other metals; but that which most of all resembles a true vegetation, is the *caput mortuum* of Glauber's spirit of nitre. This is a combination of very pure vegetable fixed alkali with vitriolic acid. If a large quantity of the latter has been employed in the distillation, and the mass is exposed to a moist air, a great number of crystallizations will take place on the surface, exactly resembling the vegetations of some kinds of shrubs. See CRYSTALLIZATION, PLANTS; GERMINATION, &c.

† See *Chymistry*, no 198.

VEGETATIVE soul, among philosophers, denotes that principle in plants by virtue of which they vegetate, or receive nourishment and grow. See the preceding article.

VEHICLE, in general, denotes any thing that carries or bears another along; but is more particularly used in pharmacy for any liquid serving to dilute some medicine, in order that it may be administered more commodiously to the patient.

VEII (anc. geog.), a city of Etruria, the long and powerful rival of Rome; distant about 100 stadia, or 12 miles, to the north-west: situated on a high and steep rock. Taken after a siege of 10 years by Camillus, six years before the taking of Rome by the Gauls; and thither the Romans, after the burning of their city, had thoughts of removing; but were dissuaded from it by Camillus, (Livy). It remained standing after the Punic war; and a colony was there settled, and its territory assigned to the soldiers. But after that it declined so gradually, as not to leave a single trace standing. Famous for the slaughter of the 300 Fabii on the Cremera, (Ovid). The spot on which it stood lies near Isola, in St Peter's patrimony, (Hollstenius).

VEIL, a piece of stuff, serving to cover or hide any thing.

In the Romish churches, in time of Lent, they have veils or curtains over the altar, crucifix, images of saints, &c.

A veil of crape is wore on the head by nuns, as a badge of their profession: the novices wear white veils, but those who have made the vows black ones. See the article NUN.

VEIN, in anatomy, is a vessel which carries the blood from the several parts of the body to the heart. See ANATOMY, n° 387.

VEIN, among miners, is that space which is bounded with woughs, and contains ore, spar, canck, clay, chert, croil, brownhen, pitcher-chert, cur, which the philosophers call the *mother of metals*, and sometimes *soil of all colours*. When it bears ore, it is called a *quick vein*; when no ore, a *dead vein*.

VELA, a remarkable cape on the coast of Terra Firma, in South America. W. Long. 73. 20. N. Lat. 12. 0.

VELARIUS, in antiquity, an officer in the court of the Roman emperors, being a kind of usher, whose post was behind the curtain in the prince's apartment, as that of the chancellor's was at the entry of the balustrade; and that of the ostiarii at the door. The velarii had a superior of the same denomination, who commanded them.

VELEZ-DE-GOMERA, a town of Africa, in the kingdom of Fez, and in the province of Eriff. It is the ancient ACARTH; which see. With a harbour and a handsome castle, where the governor resides. It is seated between two high mountains, on the coast of the Mediterranean Sea. W. Long. 5. 0. N. Lat. 35. 0.

VELITES, in the Roman army, a kind of ancient soldiery, who were armed lightly with a javelin, a cast, cuirass, and shield.

VELITRÆ (anc. geog.), the first town of the Volsci, in Latium, beyond the Mons Albanus, 20 miles to the east of Rome: afterwards a colony, which was soon after increased. Of this place was the family of Augustus, and one of the principal in it; (Suetonius).

Now

Velleius
Venice.

Now *Velletri*, in the Campania of Rome. E. Long. 13. 20. N. Lat. 41. 40.

VELLEIUS PATERCULUS. See PATERCULUS.

VELLEITY, in the school-philosophy, is usually defined a languid, cold, and remiss will. Others lay it denotes an impotence of acquiring what we desire.

VELOCITY of a BODY, denotes the quantity of motion necessary to make it run over a certain space in a given time.

VELVET, a rich kind of stuff, all silk, covered on the outside with a close, short, fine, soft shag, the other side being a very strong close tissue.

The nap or shag, called also the *velveting*, of this stuff, is formed of part of the threads of the warp, which the workman puts on a long narrow-channelled ruler or needle, which he afterwards cuts, by drawing a sharp steel tool along the channel of the needle to the ends of the warp. The principal and best manufactories of velvet are in France and Italy; particularly in Venice, Milan, Florence, Genoa, and Lucca: there are others in Holland, set up by the French refugees; whereof that at Haarlem is the most considerable: but they all come short of the beauty of those in France, and accordingly are sold for 10 or 15 per cent. less. There are even some brought from China; but they are the worst of all.

VENAL, or VENOUS, in anatomy, something that bears a relation to the veins. This word is also used for something bought with money, or procured by bribes.

VENEERING, VANEERING, or *Finearing*, a kind of marquetry or inlaying, whereby several thin slices or leaves of fine woods, of different kinds, are applied and fastened on a ground of some common wood.

VENEREAL, something belonging to venery; as the lues venerea, &c.

VENERY, is used for the act of copulation, or coition, of the two sexes.

VENERY also denotes the act or exercise of hunting wild beasts, which are also called *beasts of venery*, and *beasts of the forest*.

VENESECTION, or PHLEBOTOMY, in surgery. See SURGERY, n° 346, *et seq.*

VENETIAN BOLE, a fine red earth used in painting, and called in the colour-shops *Venetian red*.—It is dug in Carinthia, and sent from Venice to all parts of the world; but the use of it here is very much superseded by a bright collioth of vitriol.

VENICE, a celebrated city of Italy, and capital of a republic of the same name, situated on the Lagues or Small Islands, about five miles from the continent; in E. Long. 130. N. Lat. 45. 40.

The name of Venice is evidently derived from *Venetia*, one of the Roman provinces of Italy; and this again from the *Henetians*, a people of Paphlagonia, who settled in that part of the country. The city is said to have been founded about the year 451 or 452; when Attila, having destroyed the cities of Aquileia, Verona, Mantua, Treviso, &c. such of the inhabitants as escaped the slaughter, fled to the islands on their coast, and there took up their residence. Historians are profuse in their commendations of the virtue of the Venetians during the infancy of their city; and Cassiodorus informs us, that one would have taken the inhabitants rather for an assembly of philosophers, living at their ease and cultivating the

duties of religion, than for what they really were, a distressed and confused rabble who had escaped from the calamities of war. Nothing remarkable, however, occurs in the history of Venice for some time, excepting the change of government from the consular to the tribunitial form, which happened about 30 years after the building of the city. The republic first began to be of consequence after the destruction of Padua by the Lombards. About this time they were become masters of a fleet, and a body of land-forces. They engaged in a quarrel with the Lombards, of which we know not the particulars. In a short time, however, they distinguished themselves against the Istrian pirates, who had committed depredations on their coasts, and the Tergestines, or inhabitants of Trieste, who had suddenly carried off a number of the citizens of Venice. These exploits procured them a considerable degree of reputation and esteem among their neighbours; and by improving every opportunity of increasing their trade, and augmenting the number of manufactures, &c. the city very soon arrived at a high pitch of affluence and power. In the war carried on by Justinian with the Goths in Italy, the Venetians gave considerable assistance to Narles the Roman general, inasmuch that he expressed his gratitude by several rich presents, some high marks of distinction, and particularly by building two fine churches dedicated to the saints Theodore and Germanian; the oldest public buildings, beside St Mark's and St Peter's, in Venice.

From the time of Justinian to the year 697, historians are silent with regard to the Venetian affairs. A great revolution now took place in the government: the tribunaries having abused their power were abolished; and in their stead was elected a *doge* or duke, in whom was vested the supreme authority. He was to represent the honour and majesty of the state; to have respect and distinction paid him beyond what the tribunaries, or even the consuls, enjoyed: he was to assemble and preside at the great council; to have a casting-vote in all disputed points; to nominate to all offices, places, and preferments; and lastly, to enjoy the same authority in the church as in the state. This form of government was changed in 737, for what reason we govern-
ment.

Under the doges, the power and wealth of the Venetian republic continued to increase. In 764 the Heracleans and Jesulans, subjects to the republic, having formed some designs against the state, put themselves under the protection of Charlemagne. That conqueror, not finding it convenient to give them present assistance, settled them in Malamoc until he could give them more effectual succour. The Venetians, however, disregarding the protection of that powerful monarch, attacked and instantly drove them out of the place where he had settled them. Incensed at this, Charlemagne ordered his son Pepin to declare republic.

war against the republic. This was immediately done; but the blow was for some time diverted by Astolphus king of the Lombards, who, committing great devastations in the territories of the pope, obliged Pepin to come to the assistance of his holiness. However, after having afforded the necessary succour to the pope, Pepin prosecuted the war with Venice. The event is uncertain: all we know is, that about this time the Venetians declared themselves a free and independent state; which makes it probable that his success had not been great. But in 804 the war was renewed with the utmost fury. Pepin having quarrelled with Nicephorus the Greek emperor, and finding Obelerio the Venetian doge inclined to favour his adversary, determined to exterminate the very name of the republic. After having laid waste the province of Venetia, he led his army directly to Venice, blocking the city up at the same time by his fleet. The Venetians were not disheartened at the number of their enemies, the reputation of Pepin, or the civil divisions among themselves; their animosities were laid aside, and a strict union formed against the common enemy: the chief command was given to Valentin, as Obelerio was supposed too nearly allied to Pepin to fight with that good-will and cheerfulness the service of his country required. The Venetians, notwithstanding the most obstinate defence, the most vigorous sallies, and their selling every inch of ground at an incredible expense of blood, were at length reduced to that part of the city south of the Rialto; this stream, and their own bravery, being now their only defence. While Pepin was preparing to lay a bridge over the canal, they resolved, as a last effort, to attack Pepin's fleet, and to vanquish or die in defence of their liberty. Embarking all the troops they could spare, they bore down, with the advantage of the wind and tide, upon the enemy, and began the attack with such fury, as obliged the French admiral to give way. The lightness of their ships, and their knowledge of the foundations, gave the Venetians every advantage they could wish: the enemy's fleet was run aground, and the greater part of their troops perished in attempting to escape; the ships were all, to a few, either taken or destroyed. During this action at sea, Pepin resolved to assault the city by land, not doubting but the garrison was so weakened by the number of forces they had sent on board the fleet, as to be able to make but a slight resistance. Having for this purpose thrown a bridge over the Rialto, he was marching his troops across it when he found himself attacked on every side by the Venetians from their boats, and others who had posted themselves on the bridge. The battle was long, bloody, and doubtful, until the Venetians employed all their power to break down the bridge; which at last yielding to their obstinate endeavours, a prodigious slaughter of the French ensued: however, they fought like men in despair, seeing no hopes of safety but in victory; but all communication being cut off with the troops on shore, they were to a man either killed or drowned. The number of slain was so great, that the space between the Rialto and Malamoc was covered with dead bodies, and has ever since gone by a name expressive of the prodigious slaughter. Pepin was so struck with the intrepidity of the Venetians, that he raised the siege,

abandoned the enterprise, and concluded a peace with the republic: he afterwards came to Venice to intercede for Obelerio, that he might be restored; which the Venetians granted, more out of respect to the request of so great a prince, than love to the unhappy Obelerio. The people had a notion that Obelerio had encouraged Pepin to declare war upon the republic, and that a correspondence between them was carried on during the siege; Pepin was therefore no sooner withdrawn, than the populace seizing upon Obelerio, tore his body in pieces, and scattered his limbs and bowels about the city. His wife shared the same fate; for as she was the sister of Pepin, it was not doubted but her influence was the cause of her husband's perfidy.

In 839 we find the Venetians engaged in an alliance offensive and defensive against the Saracens with Michael the Greek emperor. A fleet of 60 galleys was immediately equipped, who joined the Grecian fleet and engaged the enemy; but during the heat of their engagement, the Greeks having basely deserted their allies, the Venetians were so completely defeated, that scarce a single vessel remained to carry the news of their misfortune to Venice. This defeat threw the city into the utmost consternation, as it was not doubted that the Saracens would immediately lay siege to the capital; but from these fears they were soon relieved, by certain intelligence that the Saracens had gone to Ancona, which they had pillaged and destroyed. The Narentines, however, a piratical people, no sooner heard of the defeat of the Venetians, than they laid waste the coasts of Dalmatia, and ravaged the country for a considerable way; at the same time that the city was distracted by internal dissensions and tumults, in one of which the doge was murdered.

It was not till the year 881 that the Venetian affairs were thoroughly re-established. By the prudent and vigorous administration of Orso Participato the power of the Saracens was checked, the Narentines utterly defeated, and peace and domestic tranquillity restored. From this time the republic continued to flourish; and in 903 her reputation for arms became famous all over the world by a great victory gained over the Hungarians, who had invaded Italy, defeated Berengarius, and threatened the country with total destruction. For a long time after, we meet with no remarkable transactions in the Venetian history; but in general the republic increased in wealth and power by its indefeasible application to maritime affairs and to commerce. About the year 1040 it was ordained that no prince should associate a colleague with him in the supreme power, a statute which has ever since continued unaltered.

Towards the close of the 11th century, Venice began to make a very considerable figure among the Italian states, and to carry on wars with several of them. In 1084 the republic was by the emperor of Constantinople invested with the sovereignty of Dalmatia and Croatia, which, however, had been held long before by right of conquest. As soon as the Croisade was preached up, the Venetians fitted out a principal fleet of 200 sail against the infidels; but before this armament was in a condition to put to sea, war broke out with Pisa. The doge Vitalis Michael took upon him the command of the fleet, when, after having defeated the Pisans in a bloody action at sea, he set sail

for

The French fleet entirely destroyed.

And great part of their army.

1 Venet. for Smyrna, from thence to Afcalon, at that time befiged by the Chriftians. To his valour was owing the conquest of this city, as well as thofe of Caipha and Tiberias; but before he had time to pufh his good fortune further, he was recalled on account of an invafion of the Normans in Dalmatia. Here he was equally fuccceffful: the Normans were every where defeated; and Michael returned home loaded with booty; but died foon after, to the great grief of all his fubjects. He was fucceeded by Ordelapho Faliero, under whom the Venetians affifted Baldwin in the fieve of Ptolemais, and are faid to have been the chief inftruments of its conquest; and Baldwin, in recompence for the fervices of the republic, invefted her with the fovereignty of that city, which he endowed with many extraordinary privileges, in order to render his prefent more valuable. This good fortune, however, was overbalanced by a rebellion in Dalmatia and Croatia. The former was reduced; but, in a battle with the Croats, the doge was killed, and his army entirely defeated: by which difafter the Venetians were fo much fpirited, that they clapped up a peace on the beft terms they could, giving up all thoughts of Croatia for the prefent.

22 The Venetians receive great defeat in Croatia.

Under the government of Domenico Micheli, who fucceeded Ordelapho, the Pope's nuncio arrived at Venice, and excited fuch a fpirit of enthufiafm among all ranks and degrees of men, that they ftrve whole names fhould be firft enrolled for the holy war. The doge, having fitted out a fleet of 60 galleys, failed with it to Joppa, which place the Saracens were at that time befiging. The garrifon was reduced to the laft extremity when the Venetian fleet arrived, furprifed, and defeated that of the enemy with great flaughter; foon after which the Saracens raifed the fieve with precipitation. Tyre was next befiged, and foon was obliged to capitulate; on which occafion, as well as on the taking of Afcalon, the Venetians flared two-thirds of the fpoils. But in the mean time the emperor of Conftantinople, jealous of the increafing power and wealth of the republic, refolved to make an attack upon Venice, now weakened by the abfence of the doge and fuch a powerful fleet. But the fenate, having timely notice of the emperor's intentions, recalled the doge, who infantly obeyed the fummons. Stopping at Rhodes, in his way home to refrefh and water the fleet, the inhabitants refufed to furnifh him with the neceffaries he demanded. Incenfed at this denial, he levelled their city with the ground; and from thence failing to Chios, he laid wafte and deftroyed the country, carrying off the body of St Ildore, in thofe days accounted an ineffimable treasure. After this he feized on the iflands of Samos, Lesbos, Andros, and all thofe in the Archipelago belonging to the emperor; and having reduced Zara, Spolara, and Trahu, places in Dalmatia which had revolted during his abfence, he returned in triumph to Venice, where he was received with great joy.

24 Emperor of Conftantinople refolves to attack Venice.

25 Great fucccefs of the doge againft him.

The Venetians now became very formidable throughout all Europe. The Sicilians, Paduans, with the ftates of Verona and Ferrara, felt the weight of their power; and in 1173 they ventured to oppofe Frederic Barbaroffa emperor of Germany. The occafion of this quarrel was, that Pope Alexander had taken fhelter in Venice in order to avoid the refentment of Barbaroffa,

26 Quarrel with the emperor Barbaroffa.

who had conceived an implacable averfion againft him. The Venetians difpatched ambaffadors to him; but he answered them in a rage, "Go tell your prince and people, that Frederic the Roman emperor demands his enemy, who is protected by them. If they fend him not infantly bound hand and foot, he will overturn every law, human and divine, to accomplifh his revenge; he will bring his army before their city, and fix his victorious ftandards in the market-place, which fhall float in the blood of its citizens." On the return of the ambaffadors with this terrible menace, it was agreed to equip a fleet with all expedition, and prepare for repelling the attacks of fuch a formidable and haughty enemy. But before the armament could be prepared, Otho, the emperor's fon, arrived before the city with a fleet of 75 galleys. The doge Sebastianio Ziani failed out with the few veffels he had got together, to give the enemy battle. The fleets met off the coaft of Iftria, and a terrible engagement enfued, in which the imperial fleet was totally defeated, Otho himfelf taken prifoner, and 48 of his fhips deftroyed. On the doge's return, the pope went out to meet him, and prefented him with a ring, faying, "Take this, Ziani, and give it to the fea, as a testimony of your dominion over it. Let your fucceffors annually perform the fame ceremony, that pofterity may know that your valour has purchafed this prerogative, and fubjected this element to you, even as a husband fubjecteth his wife." Otho was treated with the refpect due to his rank; and foon conceived a great friendfhip for Ziani. At laft, being permitted to vifit the imperial court on his parole, he not only prevailed on his father to make peace with the Venetians, but even to vifit their city, fo famed for its commerce and naval power. He was received with all poffible refpect, and on his departure attended to Ancona by the doge, the fenate, and whole body of the nobility. During this journey he was reconciled to the pope; and both agreed to pay the higheft honours to the doge and republic.

In the beginning of the 13th century, the Venetians, now become exceedingly powerful and opulent, by reafon of the commerce which they carried on with the richeft countries of the world, were invited by young Alexis, fon to the emperor of Conftantinople, to his father's affiftance, who had been depofed and blinded by a rebellious faction. In conjunction with the French, they undertook to reftore him; and eafily fucceeded. But the old emperor dying foon after, his fon was elefted in his room, and a few days after murdered by his own fubjects; on which the empire was feized by Myrtillus, a man of mean birth, who had been raifed by the favour of old Alexis. As the allied army of French and Venetians was encamped without the city, Myrtillus refolved immediately to drive them out of his dominions, and for this purpofe attempted to furprife their camp; but being repulfed, he fhut himfelf up in the city, with a refolution to ftand a fieve. The allies afaulted it with fo much vigour, that the ufurper was obliged to fly; and though the citizens held out after his departure, they were obliged in lefs than three months to capitulate. This proved a fource of greater acquisition to Venice than all that had yet happened. All the chief offices of the city were filled up with Venetians, in recompence for their fervices.

services: the allies entered Thrace, and subdued it; Candia, and all the Greek islands, also fell under the dominion of the republic.

33 Wars between Venice and Genoa.

In the mean time the Genoese, by their successful application to commerce, having raised themselves in such a manner as to be capable of rivalling the Venetians, a long series of wars took place between the republic; in which the Venetians generally had the advantage, though sometimes they met with terrible overthrows. These expensive and bloody quarrels undoubtedly weakened the republic in the main, notwithstanding its successes. In the year 1348, however, the Genoese were obliged to implore the protection of Visconti duke of Milan, in order to support them against their implacable enemies the Venetians. Soon after this, in the year 1352, the latter were utterly defeated, with such loss, that it was thought the city itself must have fallen into the hands of the Genoese, had they known how to improve their victory. This was in a short time followed by a peace; but from this time the power of the republic began to decline. Continual wars with the states of Italy, with the Hungarians, and their own rebellious subjects, kept the Venetians employed so that they had no leisure to oppose the Turks, whose rapid advances ought to have alarmed all Europe. After the destruction of the eastern empire, the Turks came more immediately to interfere with the republic. The consequences are related under the article TURKEY. Whatever valour might be shown by the Venetians, or whatever successes they might boast of, it is certain that the Turks ultimately prevailed; so that for some time it seemed scarce possible to resist them. What contributed also greatly to the decline of the republic, was the discovery of a passage to the East Indies by the Cape of Good Hope in 1497. To this time the greatest part of the East India goods imported into Europe passed through the hands of the Venetians; but as soon as the above-mentioned discovery took place, the carriage by the way of Alexandria almost entirely ceased. Still, however, the Venetian power was strong; and in the beginning of the 16th century they maintained a war against almost the whole power of France, Germany, and Italy; but soon after we find them entering into an alliance with some Italian states and the king of France, against the emperor. These wars, however, produced no consequences of any great moment; and in 1573 tranquillity was restored by the conclusion of a peace with the Turks. Nothing of consequence happened in the affairs of the Venetian republic till the year 1645, when the Turks made a sudden and unexpected descent on the island of Candia.

34 The Genoese put themselves under the protection of the duke of Milan.

35 Causes of the decline of the Venetian power.

The senate of Venice did not display their usual vigilance on this occasion. They had seen the immense warlike preparations going forward, and yet allowed themselves to be amused by the grand seignior's declaring war against Malta, and pretending that the armament was intended against that island. The troops landed without opposition; and the town of Candia was taken, after an oblique defence.

36 Candia invaded by the Turks.

37 Extraordinary methods taken by the Venetians to carry on the war.

This news being brought to Venice, excited an universal indignation against the Turks; and the senate resolved to defend to the utmost this valuable part of the empire. Extraordinary ways and means of raising money were fallen upon: among others, it

was proposed to sell the rank of nobility. Four citizens offered 100,000 ducats each for this honour: and, notwithstanding some opposition, this measure was at last carried. Eighty families were admitted into the grand council, and to the honour and privileges of the nobility. What an idea does this give of the wealth of the inhabitants of Venice?

The siege of Candia, the capital of the island of that name, is, in some respects, more memorable than that of any town which history, or even which poetry, has recorded. It lasted 24 years. The amazing efforts made by the republic of Venice astonished all Europe; their courage interested the gallant spirits of every nation: volunteers from every country came to Candia to exercise their valour, to acquire knowledge in the military art, and assist a brave people whom they admired.

During this famous siege, the Venetians gained many important victories over the Turkish fleet. Sometimes they were driven from the walls of Candia, and the Turkish garrison of Candia was even besieged by the Venetian fleets. Great slaughter was made of the Turkish armies; but new armies were soon found to supply their place, by a government which boasts such populous dominions, and which has despotic authority over its subjects.

Mahomet the fourth, impatient at the length of this siege, came to Negropont, that he might have more frequent opportunities of hearing from the vizir, who carried on the siege. An officer, sent with dispatches, was directed by the vizir to explain to Mahomet the manner in which he made his approaches, and to assure him that he would take all possible care to save the lives of the soldiers. The humane emperor answered, That he had sent the vizir to take the place, and not to spare the lives of the soldiers; and he was on the point of ordering the head of the officer who brought this message to be cut off, merely to quicken the vizir in his operations, and to show him how little he valued the lives of men.

In spite of the vizir's boasted parsimony, this war is said to have cost the lives of 200,000 Turks. Candia capitulated in the year 1668. The conditions on this occasion were honourably fulfilled. Morini, the Venetian general, marched out of the rubbish of this well-disputed city with the honours of war.—The expence of such a tedious war greatly exhausted the resources of Venice, which could not now repair them so quickly as formerly, when she enjoyed the rich monopoly of the Asiatic trade.

This republic remained in a state of tranquillity, endeavouring, by the arts of peace and cultivation of that share of commerce which she still retained, to fill her empty exchequer, till she was drawn into a new war, in the year 1583, by the insolence of the Ottoman court. The Venetians had for some time endeavoured, by negotiation and many conciliatory representations, to accommodate matters with the Turks; and though the haughty conduct of her enemies afforded small hopes of success, yet such was her aversion to war on the present occasion, that she still balanced, whether to bear those insults or repel them by arms; when she was brought to decision by an event which gave the greatest joy to Venice, and astonished all Europe. This was the great victory gained

Venice.

gained over the Turkish army before the walls of Vienna, by Sobieski king of Poland,

In this new war, their late General Morfini again had the command of the fleets and armies of the republic, and sustained the great reputation he had acquired in Candia. He conquered the Morea, which was ceded formerly to Venice, with some other acquisition, at the peace of Carlowitz, in the last year of the last century.

During the war of the succession, the state of Venice observed a strict neutrality. They considered that dispute as unconnected with their interests, taking care, however, to keep on foot an army on their frontiers in Italy, of sufficient force to make them respected by the contending powers. But, soon after the peace of Utrecht, the Venetians were again attacked by their old enemies the Turks; who, beholding the great European powers exhausted by their late efforts, and unable to assist the republic, thought this the favourable moment for recovering the Morea, which had been so lately ravished from them. The Turks obtained their object; and at the peace of Passarowitz, which terminated this unsuccessful war, the Venetian state yielded up the Morea; the grand seignior, on his part, restoring to them the small islands of Cerigo and Cerigotto, with some places which his troops had taken during the course of the war in Dalmatia. Those, with the islands of Corfou, Santa Maura, Zante, and Cephalonia, the remains of their dominions in the Levant, they have since fortified, at a great expence, as their only barriers against the Turk.

Since this period no essential alteration has taken place in the Venetian government, nor has there been any essential increase or diminution in the extent of their dominions. They have little to fear at present from the Turks, whose attention is sufficiently occupied by a more formidable enemy than the republic and the House of Austria united. Besides, if the Turks were more disengaged, as they have now stripped the republic of Cyprus, Candia, and their possessions in Greece, what remains in the Levant is hardly worth their attention.

The declension of Venice did not, like that of Rome, proceed from the increase of luxury, or the revolt of their own armies in the distant colonies, or from civil wars of any kind. Venice has dwindled in power and importance from causes which could not be foreseen, or guarded against by human prudence although they had been foreseen. In their present situation, there is little probability of their attempting new conquests; happy if they are allowed to remain in the quiet possession of what they have. Venice has a most formidable neighbour in the emperor, whose dominions border on those of this republic on all sides. The independency of the republic entirely depends on his moderation; or, in case he should lose that virtue, on the protection of some of the great powers of Europe.

VENICE, the capital of the republic, stands at least four miles from any part of the Terra Firma, upon a cluster of islands. Its appearance at a distance is very striking, looking like a great town half-floated by a deluge. Betwixt the city and the Terra Firma are a great many shallows, on which at low water you may

almost every where touch the bottom with a pole; but all possible care is taken to prevent their becoming dry land. On the south side of the city are also shallows; but on these there is a greater depth of water. The channels betwixt them are marked out by stakes or poles, which on the approach of an enemy would certainly be taken away. The city is divided by a vast number of canals, on which ply the gondoliers, or watermen, in their black gondolas or boats. The streets are very clean and neat, but narrow and crooked. There are no carriages, not so much as a chair, to be seen in them. Though the city, by its situation and the great number of steeples towering above the water, strikes one with admiration at a distance, yet when he is got into it, it does not answer his expectation; for excepting the square of St Mark, and a few other places, there is nothing grand or beautiful in it, at least in comparison of many other cities of Italy. Of the canals, that called *Il Canale Maggiore*, or the "great canal," is by far the largest and longest, and consequently the most beautiful. Here races are sometimes run for prizes in the gondolas. On its banks are also several stately houses. Over these canals are a great number of handsome bridges of one arch, but without any fence on either side: they are also built of white stone, with which the streets are all paved, except the Rialto over the great canal, which is all of marble, and cost the republic 250,000 ducats, the arch being 90 feet wide. The canals in summer emit a bad smell, from the great quantities of filth continually running into them. The finest gondolas are those in which the foreign ministers make their public entries, being richly decorated with gilding, painting, and sculpture. The number of islands on which the city stands, according to some, is 60; according to others, 72. The circumference is about six Italian miles; and it takes up about two hours to make the circuit of it in a gondola. The inhabitants are supposed to be about 200,000, including those of the islands Murano, La Guidecca, and those who live on board the barges. There are near 200 springs of fresh water in the city; but the water of many of them is so indifferent, that the principal families preserve rain-water in cisterns, or are supplied with water from the Brenta. The most remarkable places in the city are the ducal palace, the square, and church of St Mark, who is the tutelary saint of Venice; the mint, public library, grand arsenal, several of the palaces of the nobles, churches, convents, and hospitals. In these last is a prodigious collection of the finest paintings; Venice, in this respect, even surpassing Rome itself. The diversions of the Venetians are chiefly masquerading, especially during the carnival and other festivals; ridottos, operas, plays, which are generally wretched performances, and concerts of vocal and instrumental music. During their festivals, debauchery, riot, and licentiousness, are carried to the greatest height. The courtizans here, we are told, are absolutely lost to all sense of modesty and common decency. The grand scene of all the shows and follies of the festivals is the square of St Mark, in which bulls are sometimes baited. In the doge's palace all the high colleges hold their assemblies; but we are told by several travellers, which seems very strange, that the stairs are no better than a privy. In this palace is a small arsenal, furnished with arms against any sudden

Venice.

sudden insurrection of the people, together with a state-prison, a great many exquisite paintings, and several curiosities, among which are some *clausura castitatis*. One side of it is towards St Mark's square, and the lower gallery on that side, with the hall under the new procuratie facing it, are called the *Broglio*, where the nobility, and none else, at least while they are present, are allowed to walk. The square of St Mark is the greatest ornament of the city, and hath the form of a parallelogram. In this square, besides the church and palace of St Mark, are two towers, on one side of which is a curious clock; and the other has stairs so constructed, that one may ride up on horseback: the latter is also so high, that it is said, in a clear day, and when the gilding of the spire was fresh, it could plainly be discerned 100 miles from Venice. Opposite to the ducal palace is the public library of the commonwealth; containing a large collection of books and manuscripts, with some fine paintings, statues, and curiosities. Hard by St Mark's square is the zecca, or mint: from zecca the gold coin called *zecchino* takes its name. One of the smallest pieces of money at Venice is called *gazetta*; and the first newspapers published there, on a single leaf, having been sold for that a-piece, all kinds of newspapers were from thence styled *gazettes*. The grand arsenal is two and a half Italian miles in circuit, and contains vast quantities of naval and other warlike stores: some pretend that it could furnish arms for 10,000 horse and 100,000 foot: here are the trophies of Scanderberg and others, with the helmet of Attila, &c. The rope-walk is 444 common paces in length, and the ropes and cables are valued at 2,000,000 of silver ducats. In the foundery none but brass cannon are cast; and 100 men are generally at work in the forges. The salt-petre works here deserve a traveller's notice: there is a vessel filled with wine and water four times a-day, where the workmen, though 1000 or more, may drink as much and as often as they please. Close to the Rialto is the bank. The trade of the city at present is far short of what it was formerly. Their chief manufactures are cloth; especially scarlet, silks, looking-glasses, gold and silver stuffs, brocades, velvets, and paper, of which, and wine, oil, fruit, sweet-meats, anchovies, and several sorts of drugs used in physic and painting, the exports are still considerable. Venice has neither walls, gates, nor citadel, to defend it; its situation supplying the want of all these. In the treasury of relics is the protocol, or original manuscript, as they pretend, of St Mark's gospel: it is rarely shown; and the writing, by length of time, is so defaced, that the greatest connoisseurs in manuscripts cannot determine whether it was wrote in Greek or Latin. Besides what is properly called the city, there is a multitude of little islands lying round, which are covered with buildings, and make each of them a kind of separate town; the most considerable of which is that called *Giudecca*, or the "Jews Quarter," which is large and populous; with St Erosimo, St Helena, St Giorgio, Chiofa, Il Lido de Palestrina, Il Lido de Malamocco, and Murano: these islands are a sort of fence to the city, breaking the violence of the waves. To distinguish them from others, the Jews here must wear a bit of red cloth in their hats. The gardens in this city are few and inconsiderable. In the island of Murano are made those beautiful looking-glasses, and other glass-

Venice.

works, for which Venice is so much noted: here the family of Cornaro hath a palace, with a gallery of paintings, little short of an Italian mile in length. The salt-works in the island of Chiofa are of great benefit to the Venetians, and yield a very considerable revenue. There are several other small islands about Venice besides those we have mentioned; but they are inconsiderable.

As to the government of this state, it was, as above related, at first vested in consuls, afterwards in tribunes. About the beginning of the 8th century, a doge, or duke, was elected, and vested with unlimited power; but in 1171, the power of the doge was much abridged, and a council of 240 persons, composed of commons as well as nobles, was appointed. Soon after, under duke Marino Morosini, the present form of electing the doge was introduced. In 1296, the government became aristocratical; the privilege of sitting in the great council being then confined to the nobility, in whom alone the supreme authority at present is vested. The number of nobles amounts to about 2000. All those are members of the senate; but, according to their antiquity, some are accounted more honourable than others. One class, and that the lowest, consists of the posterity of those who, in the necessitous times of the commonwealth, purchased their nobility for 100,000 ducats. The nobles have the title of *Excellency*; and wear, at least when in the city, a black furred gown reaching to their heels, with long caps and periwigs. Some of them are so poor, that they are fain to beg of the rich. The nobility in their dominions on the continent, tho' some of them are of very ancient families, are excluded from all offices, and treated with great insolence and contempt by their haughty lords. At the head of the government is the doge, whose office was once hereditary and power absolute; but the former is now elective, and the latter very much circumscribed: indeed he is no more than a gaudy slave, loaded with fetters, which one would think could not be much the lighter for being gilt; yet so much is the human heart captivated with external pomp and pageantry, that the office, for the most part, is eagerly sought after: but should one otherwise inclined be chosen, he cannot decline it, without exposing himself to banishment and confiscation of his effects. Though the power of the doge is very small, his state and retinue are very splendid: his title is that of *Serenity*, and his office for life: he is said to be a king with regard to his robes, a senator in the council-house, a prisoner in the city, and a private man out of it. The yearly revenue of his office is about 4000*l.*; and though he may be deposed, he cannot resign his dignity. All the nobility have a seat in the great council, unless they are under 25 years of age. In this council the supreme authority and legislative power is vested. Next to it is the senate, or *pregradi*, which consists of about 250 members, who have the power of making peace or war, and foreign alliances; of appointing ambassadors; fixing the standard of the coins; imposing duties and taxes; and all offices by sea and land are in their gift. The third council consists of the doge and his six counsellors, in which all letters and instruments relating to the state are read, ambassadors admitted to audience, and other important affairs transacted. The other colleges are the council of ten; which decides all criminal

47
Govern-
ment, &c
of Venice

cases

Venice.

cases without appeal, and to which even the doge himself is subject: the procurators of St Mark, whose office is very lucrative; and who decide with respect to wills, guardianships, and the making a proper provision for the poor; and the state-inquisition, whose business it is to provide for the public tranquillity. In the wall of the ducal palace are heads of lions and leopards, with open mouths, to receive informations of any plot or treason against the state. The ecclesiastical, or *holy inquisition* as it is called; but the power of this court, so formidable in other countries, is here under great restrictions. Here is also a particular college for the regulation of dress, but their jurisdiction does not extend to strangers. The method of electing the doge is no less singular than complicated; and effectually calculated to prevent all kind of bribery or corruption. All the members of the grand council who are past 30 years of age, being assembled in the hall of the palace, as many balls are put into an urn as there are members present; 30 of these balls are gilt, and the rest white. Each councillor draws one; and those who get the gilt balls go into another room, where there is an urn containing 30 balls, nine of which are gilt. The 30 members draw again; and those who by a second piece of good fortune get the gilt balls, are the first electors, and have a right to choose 40, among whom they comprehend themselves.

47
Method of
choosing the
doge.

Those 40, by balloting in the same manner as in the former instances, are reduced to 12 second electors, who choose 25, the first of the 12 naming three, and the remaining 11 two a piece. All those being assembled in a chamber apart, each of them draws a ball from an urn containing 25 balls, among which are 9 gilt. This reduces them to 9 third electors, each of whom chooses five, making in all 45; who, as in the preceding instances, are reduced by ballot to 11 fourth electors, and they have the nomination of 41, who are the direct electors of the doge. Being shut up by themselves, they begin by choosing three chiefs, and two secretaries; each elector being then called, throws a little billet into an urn which stands on a table before the chiefs. On this billet is inscribed the person's name whom the elector wishes to be doge.

The secretaries then, in the presence of the chiefs, and of the whole assembly, open the billets. Among all the 41 there are generally but a very few different names; as the election for the most part balances between two or three candidates. Their names, whatever is the number, are put into another urn, and drawn out one after another. As soon as a name is extracted the secretary reads it, and if the person to whom it belongs is present, he immediately retires. One of the chiefs then demands with a loud voice, whether any crime can be laid to this person's charge, or any objection made to his being raised to the sovereign dignity? If any objection is made, the accused is called in and heard in his own defence; after which the electors proceed to give their decision, by throwing a ball into one of the two boxes, one of which is for the Ayes, the other for the Noes. The secretaries then count the balls; and if there are 25 in the first, the election is finished; if not, another name is read, and the same inquisition made as before, till there are 25 appearing balls.

49
Order of
knighthood

The principal Venetian order of knight-hood is that
Vol. X.

of St Mark; the badge of which is a large gold medal dependent on the breast. The order of Constantine knights wear a cross hanging from a gold chain.

With respect to religion, that of the Venetians is the Roman Catholic; but they are no bigots. We have already observed, that the court of inquisition here is under very great restrictions; and the pope is considered as little more than a temporal prince, his supremacy being rejected.

The Venetians are still the greatest naval power in Italy. They pretend they could fit out, in case of necessity, 60 men of war, 100 galleys, and to galeasses; Military revenues. though one can hardly imagine how they could man force and half that number. The army is said to consist of between 20,000 and 30,000 men; the greatest part of which are Dalmatians and Switzers. The commander in chief, styled *Capitano*, is always a foreigner of distinction. General Græme, a Scotchman, lately enjoyed that honourable post. The ordinary revenues of the state are computed at about 1,200,000 l. sterling; but in time of war they can raise them greatly. A considerable part of the revenue arises from the customs, and the duty on salt made at Corfu and Chiozza.

VENIRE FACIAS, in law, is a judicial writ lying where two parties plead and come to issue; directed to the sheriff, to cause 12 men of the same neighbourhood to meet and try the same, and to say the truth upon the issue taken.

VENTER, signifies the belly; but it is also used for the children by a woman of one marriage: there is in law a first and second venter, &c. where a man hath children by several wives; and how they shall take in descents of lands.

VENTER *Inspicendo*, is a writ to search a woman that saith she is with child, and thereby withholdeth lands from the next heir: the trial whereof is by a jury of women.

VENTILATOR, a well known machine, by which the noxious air of any confined place, as an hospital, goal, ship, chamber, &c. may be changed for fresh air.

VENTRICLE, properly denotes any little cavity; but is more particularly used by physicians and anatomists, for the stomach, and certain cavities of the heart and brain.

VENTRILOQUOUS, a term applied to persons who speak inwardly; having a peculiar art of forming speech, by drawing the air into the lungs, so that the voice, proceeding out of the thorax, to a by-stander seems to come from a distance. The word is compounded of *venter*, "belly;" and *loquor*, "I speak."

VENUS, in pagan worship, the goddess of love and beauty. Cicero mentions two other deities of this name; Venus, styled *Urania* and *Celestis*; and the *Venus Pandemos*, or *Popularis*, the wife of Vulcan, and the goddess of wanton and effeminate love. To the first the Pagans ascribed no attributes but such as were agreeable to the strictest chastity and virtue; and of this deity they admitted no corporeal resemblance, the being only represented by the form of a globe, ending conically. Her sacrifices were termed *nephelia*, on account of their sobriety. To her honey and wine were offered, and no animal except the heifer; and on her altars the wood of figs, vines, or mulberries, were not suffered to be burnt. The Romans dedicated a temple to this goddess, to whom they gave the name of *Venturdia*;

ficordia; because he turned the hearts of lewd women, and inspired modesty and virtue.

But the most famous of these goddesses is the wife of Vulcan; who is represented as springing from the froth raised by the genitals of Saturn, when cut off by Jupiter and thrown into the sea. As soon as she was formed, she was laid in a beautiful shell embellished with pearl, and wafted by gentle zephyrs to the isle of Cythera, whence she failed to Cyprus. At her landing, flowers rose beneath her feet: she was received by the Hours, who braided her hair with golden fillets; and then wafted her to heaven, where her charms appeared so attractive, that most of the gods desired her in marriage; but Vulcan, by the advice of Jupiter, gained possession by putting poppies into her necker. As Venus was the goddess of love and pleasure, the poets have been lavish in the description of her beauties; and the painters and statuary have endeavoured to give her the most lovely form. Sometimes she is represented clothed in purple, glittering with gems, her head crowned with roses, and drawn in an ivory car by swans, doves, or sparrows; at others, she stands attended by the Graces; but in all positions, her son Cupid is her inseparable companion. She was honoured as the mother of Hymeneus, Cupid, Æneas, and the Graces, and was passionately fond of Adonis and Anchises.

This goddess was principally worshipped at Paphos and Cyprus; and the sacrifices offered to her were white goats and swine, with libations of wine, milk, and honey. Her victims were crowned with flowers, or wreaths of myrtle.

Venus's Fly-Trap. See *DIONEÆ Muscipula*.

VENUS, in zoology, a genus of insects belonging to the order of vermes testacea. Its animal is a tethys; the hinge with three teeth near each other, one placed longitudinally and bent inwards. There are a great many species; of which the most remarkable is the merenaria, or commercial, with a strong, thick, weighty shell, covered with a brown epidermis; pure white within; slightly striated transversely. Circumference above 11 inches. These are called in North America *clams*; they differ from other species only in having a purple tinge within. Wampum, or Indian money, is made of them.

VEPRECLÆ, diminutive from *vepres*, a "briar, or bramble;" the name of the 31st order in Linnæus's Fragments of a Natural Method. See BOTANY, p. 1311.

VERA-CRUZ, a sea-port town of North America, in New Spain, with a very secure and commodious harbour, defended by a fort. Here the Flotilla annually arrives from Spain to receive the produce of the gold and silver mines of Mexico. And at the same time a fair is held here, for all manner of rich merchandize brought from China and the East Indies by way of the South Sea, and for the merchandize of Europe by the way of the Atlantic Ocean. This town is not two miles in circumference; and about it there is a wall of no great strength on the land-side. The air is unwholesome; and there are very few Spaniards here unless when the Flotilla arrives, and then it is crowded with people from all parts of Spanish America. It is 200 miles south-east of Mexico. W. Long. 102, 15. N. Lat. 18. 41,

Veratrum
Verd.

VERAGUA, a province of New Spain, bounded on the east by that of Costa Rica, on the west by Panama, on the north by Darien and the Gulph of Mexico, and on the south by the South Sea. It is about 125 miles in length from east to west, and 60 in breadth from north to south. It is a mountainous barren country; but has plenty of gold and silver. Conception is the capital town.

VERATRUM, WHITE HELLBORE; a genus of the monoclea order, belonging to the polygama class of plants. There are four species.

The root of the *album*, or white hellebore, promotes violent sneezing, and is mixed in ointments, to cure the itch. It is never now given inwardly. Boerhaave very justly observes, that it is a medicine much fitter for horses than men. It is administered as a sternutatory, with great success, in apoplexies and lethargic complaints.

VERB, in grammar. See GRAMMAR.

VERBASCUM, MULLEIN; a genus of the monogynia order, belonging to the pentandria class of plants. There are 12 species, of which the most remarkable are, 1. The thapsus or great mullein, with downy leaves running along the stem, and yellow blossoms, terminating in a long spike. It is a native of Britain, growing commonly on dry banks of ditches. Externally used it is an emollient, and its leaves are by some reckoned a specific for the piles. It is said to intoxicate fish so that they may be taken with the hand. In Norway it is given to cows that are consumptive. The down serves for tinder. Neither cows, goats, sheep, horses, nor swine, willingly eat of it. 2. The nigrum, or black mullein, having a stem beset with hairs that are beautifully branched; the blossoms yellow, with purple tips. This is also a native of Britain, growing under hedges, and by road-sides. It is a beautiful plant, and the flowers are grateful to bees: swine eat it; sheep are not fond of it; cows, horses, and goats, refuse it.

VERBENA, VERVAIN; a genus of the monogynia order, belonging to the diandria class of plants. There are 18 species; of which the most remarkable is the officinalis, or common vervain, growing on the road-sides near towns and villages. The leaves have many jagged clefts, the blossoms are pale blue. It manifests a slight degree of astringency, and was formerly much in vogue as a decoctifluent; but is now disregarded. Mr Millar says that it is never found above a quarter of a mile from a house; whence the common people in England call it *Simpler's joy*, because wherever it is found, it is a certain sign of a house being near. Sheep eat it; cows, horses, and goats, refuse it.

VERCELLÆ, (anc. geog.); a town of the Libici, in the Transpadana, on the right or west side of the river Sessia, near the Campi Raudii, where Marius gave a signal defeat to the Cimbrici, (Plutarch). Now *Vercelli* in Piedmont, situated on the river Sesia. E. Long. 8° 20', Lat. 45° 15'.

VERD (Cape), a promontory on the west coast of Africa, 40 miles north-west of the mouth of the river Gambiæ. W. Long. 17. 49. N. Lat. 15. 0.

VERD, the islands of Cape de Verd, are seated on the Atlantic Ocean, about 400 miles west of the Cape. They are between the 13th and 19th degree of latitude; and the principal are ten in number, lying in

Verden
Verdigrife.

Verdict.

a semi-circle. Their names are, *St Antony, St Vincent, St Lucia, St Nicholas, the Isle of Sal, Bona Vista, Mayo, St Jago, Fuego, and Brava.*

VERDEN, a considerable town of Germany, in the circle of Westphalia, and capital of a duchy of the same name, subject to the elector of Hanover. It is seated on the river Aller near the Wefer, in W. Long. 9. 10. N. Lat. 53. 30.

VERDUN, a town of France, in Lorraine, and capital of Verdunois, with a bishop's see. There are several abbeys, collegiate and parish churches; but the principal structures are the bishop's palace and the town-house. They make large quantities of sweetmeats here, which are exported to several places. E. Long. 5. 24. N. Lat. 49. 0.

VERDIGRISE, a kind of rust of copper, much used by painters as a green colour. It is chiefly manufactured at Montpellier; the vines of Languedoc being very convenient for this purpose.

The following process for making verdigrise is described by Mr Monet of the royal society of Montpellier, and is published among the memoirs of the academy for the years 1750 and 1753.

Vine-stalks well dried in the sun are steeped during eight days in strong wine, and afterwards drained. They are then put into earthen-pots, and upon them wine is poured. The pots are carefully covered. The wine undergoes the acetous fermentation, which in summer is finished in seven or eight days; but requires a longer time in winter, although this operation is always performed in cellars. When the fermentation is sufficiently advanced, which may be known by observing the inner surface of the lids of the pots, which during the progress of the fermentation is continually wetted by the moisture of the rising vapours, the stalks are then to be taken out of the pots. These stalks are by this method impregnated with all the acid of the wine, and the remaining liquor is but a very weak vinegar. The stalks are to be drained during some time in baskets, and layers of them are to be put into earthen-pots with plate of Swedish copper, so disposed that each plate shall rest upon and be covered with layers of stalks. The pots are to be covered with lids; and the copper is thus left exposed to the action of the vinegar, during three or four days or more, in which time the plates become covered with verdigrise. The plates are then to be taken out of the pots, and left in the cellar three or four days; at the end of which time they are to be moistened with water, or with the weak vinegar above-mentioned, and left to dry. When this moistening and drying of the plates has been thrice repeated, the verdigrise will be found to have considerably increased in quantity; and it may then be scraped off for sale.

A solution or erosion of copper, and consequently a verdigrise, may be prepared by employing ordinary vinegar instead of wine, as is directed in the above process. But it would not have the usefulness of ordinary verdigrise, which quality is necessary in painting. Good verdigrise must be prepared by means of a vinous acid, or solvent, half acid and half spirituous. Accordingly, the success of the operation depends chiefly on the degree of fermentation to which the wine employed has been carried: for this fermentation must not have been so far advanced that

no sensibly vinous or spirituous parts remained in the liquor.

Verdigrife taken internally is a very violent emetic, and is reckoned among the poisons, though it is certainly the mildest of that pernicious tribe. It seems to act less as a corrosive than as a violent allstringent, which renders it so disagreeable to the stomach that it is almost instantly evacuated by vomit.—In very small doses it has been given as an emetic, and in this intention it operates most powerfully and speedily. Many pernicious consequences have been attributed to the gradual introduction of small quantities of verdigrise or copper into the human body: but it is much to be doubted whether this would certainly be accounted the cause of them; since copper, either by itself or dissolved either in acid or alkali, when it does not prove emetic, always acts as a tonic.

VERDICT, (*Vere dictum*), is the answer of the jury given to the court concerning the matter of fact, in any case civil or criminal, committed by the court to their trial and examination. See LAW, N^o clxxxvi. 51.

In the law of England, a verdict is either *privy* or *public*. A *privy verdict* is either when the judge hath left or adjourned the court; and the jury, being agreed in order to be delivered from their confinement, obtain liberty to give their verdict privily to the judge out of court: which *privy verdict* is of no force, unless afterwards affirmed by a public verdict given openly in court; wherein the jury may, if they please, vary from their *privy verdict*. So that the *privy verdict* is indeed a mere nullity; and yet it is a dangerous practice, allowing time for the parties to tamper with the jury, and therefore very seldom indulged. But the only effectual and legal verdict is the public verdict; in which they openly declare to have found the issue for the plaintiff, or for the defendant; and if for the plaintiff, they assess the damages also sustained by the plaintiff, in consequence of the injury upon which the action is brought.

Sometimes, if there arises in the case any difficult matter of law, the jury, for the sake of better information, and to avoid the danger of having their verdict attained, will find a special verdict; which is grounded on the statute Westm. 2. 13 Edw. I. c. 30. § 2. And herein they state the naked facts, as they find them to be proved, and pray the advice of the court thereon; concluding conditionally, that if upon the whole matter the court shall be of opinion that the plaintiff had cause of action, they then find for the plaintiff; if otherwise, then for the defendant. This is entered at length on the record, and afterwards argued and determined in the court at Westminster, from whence the issue came to be tried.

Another method of finding a species of special verdict, is when the jury find a verdict generally for the plaintiff, but subject nevertheless to the opinion of the judge or the court above, on a special case stated by the counsel on both sides with regard to a matter of law: which has this advantage over a special verdict, that it is attended with much less expence, and obtains a much speedier decision; the *posse* being stayed in the hands of the officer of *nisi prius* till the question is determined, and the verdict is then entered for the plaintiff or defendant as the case may happen. But as nothing appears upon the record but the general verdict, the parties are precluded hereby from the bene-

fit of a writ of error, if dissatisfied with the judgment of the court or judge upon the point of law. Which makes it a thing to be wished, that a method could be devised of either lessening the expence of special verdicts, or else of entering the case at length upon the *posse*. But in both these instances the jury may, if they think proper, take upon themselves to determine, at their own hazard, the complicated question of fact and law; and, without either special verdict or special case, may find a verdict absolutely either for the plaintiff or defendant.

In criminal cases, the jury deliver in their verdict with the same forms as in civil causes: only they cannot, in a criminal case which touches life or member, give a privy verdict. But an open verdict may be either general, guilty, or not guilty; or special, setting forth all the circumstances of the case, and praying the judgment of the court, whether, for instance, on the facts stated, it be murder, manslaughter, or no crime at all. This is where they doubt the matter of law, and therefore choose to leave it to the determination of the court; though they have an unquestionable right of determining upon all the circumstances, and finding a general verdict, if they think proper so to hazard a breach of their oaths: and, if their verdict be notoriously wrong, they may be punished and the verdict set aside by attain at the suit of the king; but not at the suit of the prisoner. But the practice, heretofore in use, of finding, imprisoning, or otherwise punishing jurors, merely at the discretion of the court, for finding their verdict contrary to the direction of the judge, was arbitrary, unconstitutional, and illegal; and is treated as such by Sir Thomas Smith 200 years ago; who accounted "such doings to be very violent, tyrannical, and contrary to the liberty and custom of the realm of England." For, as Sir Matthew Hale well observes, it would be a most unhappy case for the judge himself, if the prisoner's fate depended upon his directions:—unhappy also for the prisoner; for if the judge's opinion must rule the verdict, the trial by jury would be useless. Yet in many instances, where, contrary to evidence, the jury have found the prisoner guilty, their verdict hath been mercifully set aside, and a new trial granted by the court of king's bench; for in such case, as hath been said, it cannot be set right by attain. But there hath yet been no instance of granting a new trial, where the prisoner was acquitted upon the first.

VERDITER, or VERDATER, a kind of mineral substance, sometimes used by the painters, &c. for a blue; but more usually mixed with a yellow for a green colour. See CHEMISTRY, n° 201.

VERE (Sir Francis), a renowned English general, was the second son of Geoffrey de Vere, a branch of the ancient family of that name, earls of Oxford, and was born in the year 1554. Concerning his education we are uninformed. About the age of 31 he embarked with the troops sent by queen Elizabeth, under the command of the earl of Leicester, to the assistance of the states of Holland; in which service his courage and military genius became immediately conspicuous: but his gallant behaviour in the defence of Berghen-op-Zoom, in the year 1588, when besieged by the prince of Parma, established his reputation. After the siege

was raised, he received the honour of knighthood from lord Willoughby, who succeeded the earl of Leicester in the command. He continued in the service of the states till about the year 1595; during which time, namely, in 1593, he was elected member of parliament for Leominster in Herefordshire. The famous expedition against Cadiz being resolved upon, Sir Francis Vere was called home, and appointed to a principal command under the earl of Essex. The success of this enterprise is universally known. In 1597 we find him again in Holland, present at the battle of Turnhout, of which he has given a particular description in his commentaries. In the same year he embarked, with the earl of Essex, in the expedition to the Azores; and at his return was appointed governor of the Briel in Holland, with the command of the English troops in the service of the states. In 1600 he was one of the three generals at the battle of Newport, and had the honour of having the victory universally ascribed to his conduct and resolution. The states of Holland, then at war with Spain, marched their army with an intention to besiege Newport in Flanders. The commanders were, count Ernest of Nassau, count Somes, and Sir Francis Vere. The Spaniards marched to intercept them, and this battle ensued. Sir Francis was shot first through the leg, and then through the same thigh; notwithstanding which, he rallied the flying army, and led them on to victory. The Spaniards lost 120 ensigns, and most of their foot were slain. Queen Elizabeth on this occasion declared him the *worthiest captain of her time*. See *Letters of the Sidney family*, vol. ii. p. 104.—But the last and most glorious achievement of his life was his gallant defence of Ostend, with about 1600 men against an army of 12,000, from July 1601 until March 1602, when he resigned the government, and returned to Holland. An account of this memorable siege, which lasted above three years, to the destruction of the best troops of Holland, Spain, France, England, Scotland, and Italy, the reader may see in *Vere's Commentaries*, with the Continuation at the end. Queen Elizabeth died in the year 1603: the peaceful James acceded to the throne; and Sir Francis Vere, with all the heroes of his time, sheathed his sword. He died in 1608, in the 54th year of his age; and was buried in St John's chapel in Westminster abbey, where a splendid monument was erected to his memory. He married the daughter of — Dent, a citizen of London, by whom he had three sons and two daughters, none of which survived him. He will ever be remembered by posterity as one of our greatest heroes of our most heroic age.—The work above-mentioned is intitled, "The commentaries of Sir Francis Vere, being diverse pieces of service wherein he had command; written by himself in way of commentary." Cambridge 1657, folio. It is elegantly printed, and adorned with prints of Sir Francis, Sir Horace Vere, Sir John Ogle, maps, and plans of battles, &c.

VERGE, (*Virgata*), in law, signifies the compass of the king's court, which bounds the jurisdiction of the lord steward of the household; and which is thought to have been 12 miles round.

The term verge is also used for a stick or rod, whereby one is admitted tenant to a copyhold estate, by

Vergers
Veronica.

by holding it in his hand, and swearing fealty to the lord of the manor.

VERGERS, certain officers of the courts of king's bench, and common-pleas, whose business it is to carry white wands before the judges.

There are also vergers of cathedrals, who carry a rod tipped with silver before the bishop, dean, &c.

VERGIL (Polydore). See **VIRGIL**.

VERJUICE, a liquor obtained from grapes or apples, unfit for wine or cyder; or from sweet ones, whilst yet acid and unripe. Its chief use is in sauces, ragouts, &c, tho' it is also an ingredient in some medicinal compositions, and is used by the wax-chandlers to purify their wax.

VERMEYEN (John Cornelius), a Dutch historian, and portrait-painter. He attended the emperor Charles V. and drew his encampments, sieges, and battles, on the spot, from which designs the famous tapestries at the Escorial at Madrid were made. He died in 1559.

VERMICELLI, or **VERMICHELLY**, a composition of flour, cheese, yolks of eggs, sugar, and saffron, reduced to a paste, and formed into long slender pieces like worms, by forcing it with a piston thro' a number of little holes.

It was first brought from Italy, where it is in great vogue: it is chiefly used in soups and pottages, to provoke venery, &c.

VERMICULAR, an epithet given to any thing that bears a relation or resemblance to worms.

VERMIFORMIS, in anatomy, a term applied to various parts in the human body, bearing some resemblance to worms.

VERMILION, a very bright and beautiful red colour, composed of quicksilver and sulphur, in great esteem among the ancients under the name of *minium*; but what goes by the name of minium amongst us, is a preparation of lead, known also by the name of *red-lead*. See **CHEMISTRY**, n° 474.

VERMIN, a collective name, including all kinds of little animals or insects, which are hurtful or troublesome to mankind, beasts, or fruits, &c. as worms, lice, fleas, caterpillars, ants, flies, &c.

VERNACULAR, a word applied to something that is peculiar to any one country.

VERNAL, something belonging to the spring-season.

VERONA, a city of Italy, capital of the Veronese in the territory of Venice, situated near the mountains on the river Adige, in E. Long. 11. 15. N. Lat. 45. 20. It is seven miles in compass; and has been so fortified by the Venetians, that it is now looked upon as impregnable.

VERONESE, a territory of Italy, in the republic of Venice, bounded on the north by the Trentino, on the east by the Vicentino and Paduano, on the south by the Mantuano, and on the west by the Bresciano. It is about 35 miles in length, and 27 in breadth; and is one of the most fertile countries in Italy, abounding in corn, wine, fruits, and cattle.

VERONESE. See **CAGLIARI**.

VERONICA, **MALE SPEEDWELL**; a genus of the monogynia order, belonging to the diandria class of plants. There are a great number of species, of which the most remarkable are, 1. The officinalis, com-

mon male speedwell, or fluellin; a native of Britain, growing on heaths and barren grounds. The blossoms are blue, the leaves elliptical, serrated, and hairy. The leaves have a small degree of astringency, and are somewhat bitter. An infusion of them is recommended by Hoffman as a substitute for tea; but is more astringent and less grateful. The herb was formerly esteemed in medicine for various disorders, but is now almost totally disused. Cows, sheep, goats, and horses, eat it; swine refuse it. 2. The beccabunga, or common brook-lime, found in ditches and rivulets. The leaves are mild and succulent, and are eaten in salads along with other early springing plants. Cows, goats, and horses, eat it; swine refuse it.

VERROCHIO (Andrea), a Florentine, born in 1432. He was well skilled in mathematics, music, architecture, sculpture, and painting; and was the first who discovered the art of moulding off the features of the face in plaster of Paris. He died in 1488.

VERSAILLES, a town situated four leagues from Paris to the south-west. Here Lewis XIV. built a most magnificent palace, and adorned it with noble gardens: it stands on a rising ground, in the middle of a valley surrounded with hills, having, on the side towards Paris, a fine avenue leading to it through the town, which it divides into the Old and New. To give a particular account of this palace would exceed our limits; suffice it to say, that it consists of several courts embellished (both within and without) in the most sumptuous manner. The grove here is exceedingly beautiful, and the water-works very grand. The menagerie consists of seven courts, and contains a vast number of rare animals. In the palace, all the parts in the inside, that are not hung with tapestries, are lined with marble; and the nearer you come to the king's apartments, the more costly is the marble, and the finer the sculpture and painting. It would require volumes to describe the various paintings and antique statues with which all the apartments abound. The chapel is an exquisite piece of architecture, sculpture, and painting. Of all the apartments, the king's bed-chamber is the most magnificent; the bed, which is of crimson velvet, embroidered with gold, standing in a kind of alcove, where are two figures of Fame represented sitting. The canal in the garden, by which the river Eure is conveyed to it, is a very noble one: the orangery or green-house is accounted a fine piece of architecture, and indeed a master-piece of its kind; the parterre before it also is very beautiful, being adorned with a great number of orange and lemon trees, myrtles, laurels, &c. The labyrinth or maze is a fine grove, so called, because its several walks are so interwoven with each other, that it would be a difficult matter for a person to find his way out of it without a guide: in short, the garden, for statues, canals, groves, grottos, fountains, and every thing that can render it delightful, is superior to any thing of the kind in Europe. The royal cabinet contains the choicest medals, coins, paintings, &c. that Italy could afford. The stables, for proportion, convenience, beauty, and architecture, far exceed many royal palaces. In the same park stands the fine palace of Trianon; the outside of which consists wholly of variegated marble, of exquisite workmanship. The gardens

Verrochio
Versailles.

Verse
||
Vertue.

dens are large, and abound in statues and water-works. E. Long. 2. 12. N. Lat. 48. 48.

VERSE, in poetry, a line consisting of a number of long and short syllables, which run with an agreeable cadence.

VERSE is also used for a part of a chapter, section, &c.

VERSIFICATION, the art or manner of making verse; also the tune and cadence of verse. See POETRY, Part III.

VERSION, a translation of some book or writing out of one language into another.

VERT, in heraldry, the term for a green colour. It is called *vert* in the blazon of the coats of all under the degree of nobles; but in coats of nobility it is called *emerald*; and in those of kings, *verus*. In engraving it is expressed by diagonals, or lines drawn athwart from right to left, from the dexter chief corner to the sinister base.

VERTEBRÆ, in anatomy. See there, n° 29—33.

VERTEX, in anatomy, denotes the crown of the head. Hence vertex is also used figuratively for the top of other things: thus we say, the vertex of a cone, pyramid, &c.

VERTEX, is also used in astronomy for the point of the heaven directly over our heads, properly called the *zenith*.

VERTICILLATÆ, the name of a class in Ray's and Boerhaave's Methods, consisting of herbaceous vegetables, having four naked seeds, and the flowers placed in whorls round the stalk. The term is synonymous to the *labiati*, or lip-flowers of Tournefort; and is exemplified in mint, thyme, and savory.

VERTICILLATÆ is also the name of the 42d order in Linnæus's Fragments of a Natural Method, consisting of plants which answer the above description.

VERTICILLUS, a mode of flowering, in which the flowers are produced in rings at each joint of the stem, with very short foot-stalks. The term is exemplified in mint, hore-hound, and the other plants of the natural order described above.

VERTICITY, is that property of the loadstone whereby it turns or directs itself to one particular point.

VERTIGO, in medicine. See there, n° 182.

VERUMONTANUM, in anatomy. See there, n° 371, m.

VERVAIN, in botany. See VERBENA.

VERTOT d'AUBOEF (René Aubert de), a celebrated historian, was descended from a noble and ancient family in Normandy, and born in 1655. At 16 years of age he became a Franciscan friar; afterwards he entered into the order of the Premonstratenses, in which he had several benefices; and at length was a secular ecclesiastic. He became secretary to the dukes of Orleans, member of the Academy of Inscriptions, and historiographer of Malta. He died at Paris in 1735. His principal works are, 1. The History of the Revolutions of Sweden. 2. The Revolutions of Portugal. 3. The Revolutions of the Romans. 4. The History of Malta. These works are written in elegant French, and translated into most of the languages of Europe.

VERTUE (George), an eminent engraver, was born in London in the year 1684, where he was put apprentice to an engraver of arms; but his genius and

spirit prompting him to appear in a higher sphere, he applied himself with great assiduity to learn the art of drawing, in which he became a good proficient. He afterwards commenced engraver; and though greatly restrained by the native modesty of his temper, made a considerable figure in that business, particularly in engraving of portraits, in which he carried the art to greater perfection than any English engraver had done before him, and for the greatest part of his life had no equal in this kingdom. Sir Godfrey Kneller was his first patron; and he was afterwards encouraged by lord Somers, the earl of Winchester, the lord Colemaine, the lord Oxford, &c. and the late prince of Wales. His works are numerous. They are generally faithfully copied, and highly finished; and though they are far from equalling the works of some of our present engravers, they are not destitute of merit. Vertue was an antiquarian; and has redeemed from obscurity many valuable remains of antiquity. He died in 1756, and was buried in the cloisters of Westminster abbey. He was a very amiable man in private life; and was much esteemed by his friends for his piety, modesty, simplicity, and candour.

VERULAM. See BACON.

VESALIUS (Andreas), a celebrated physician and anatomist, was born at Brussels about the year 1512. He studied physic at Paris under James Sylvius; but applied himself chiefly to anatomy, which was then very little known, dissections being esteemed unlawful and impious: and it appears from his work *De humana corporis fabrica*, that he perfected himself in this useful knowledge very early. About the year 1537, the republic of Venice made him professor in the university of Padua, where he taught anatomy for seven years; Charles V. called him to be his physician, as he was also to Philip II. king of Spain. Vesalius was now at the height of his glory, when all of a sudden he formed the design of taking a journey to Palestine; concerning which journey we are told the following story. A young Spanish nobleman he attended being believed to be dead, Vesalius obtained leave to open him to explore the true cause of his illness; but when he opened the breast, he perceived symptoms of life, and saw the heart beat. The parents, not satisfied with prosecuting him for murder, accused him of impiety to the inquisition, in hopes that tribunal would punish him with greater rigour; but the king interposing, saved him on condition of his making a pilgrimage to the Holy Land. He was shipwrecked on his return, and thrown upon the island of Zante, where he perished, in 1564. He was the author of several works, the principal of which is *De humani corporis fabrica*.

VESICATORIUM, a BLISTER; an application of an acrid nature made to any part of the body, in order to draw a flux of humours to that part, and thus elevate the scarf-skin into a blister.

VESPA, the wasp; a genus of insects belonging to the order of hymenoptera. The mouth consists of two jaws without any proboscis; the superior wings are plaited; the eyes are lunar; and there is a sharp sting in the tail. There are 28 species.

The crabro, or large wasp, makes its nest in the trunks of hollow trees, and in the timber work of lofts. Its cakes or combs are composed of a substance like unto coarse paper, or rusty parchment.

Verulam
||
Velpa.

Vespa.

It is very voracious, devouring other insects, and even bees.

Of these insects, some live in society, others are solitary. A distinguishing character of this genus of flies is, their bodies being smooth and apparently without hairs. Their upper wings, when at rest, are folded in two, the whole length of them. At the rise of each of these wings is situated a scaly part, which performs the office of a spring to hinder the upper wing from rising too high, in the flapping of their wings; a caution very important to those carnivorous insects, who pursue their prey on full stretch of wing.

The common domestic or subterraneous wasps, raise buildings, live in associations, feed on plunder, and commit great outrages on our wall-fruit. This numerous commonwealth is founded by a single female impregnated during the autumn, and that has weathered out the severity of the winter. It digs a hole in a dry soil, contrives itself a sinuous inlet, or else it takes up with the dwelling place of a mole, where it hastily builds a few cells and deposits its eggs. Within the space of 20 days, they have gone through the different states of larvæ, chrysalids, and turned to wasps. Nature all-wise provides for every thing. The mule-wasps, or that are of no sex, are the only ones that labour at laying the foundation of the republic. The first eggs that are hatched prove to be neuter-wasps. No sooner are they come into existence, than they fall to work, enlarge the hole, and go about upon wood, lattice-work, and window sashes, in search of materials for building. With their teeth they cut, hack, and tear off small fibres of wood, which they moisten with a liquor they disgorge, and then convey them to the work-shop. Other labourers are in waiting for them, who with those materials set about the construction of the wasp-nest, an edifice outwardly composed of sheets of paper, which not being in contact with each other, dampness cannot penetrate to the inside. This latter part consists of 12 or 15 stories, and between each runs a colonnade formed by the fastenings which connect the cakes one to the other. Every story is as it were a market-place, where the citizens may take their walks. Their cells are hexagonal, and form the cradle in which the mother continues to lay eggs of neuter-wasps to the number of 15,000 or 16,000; after which it deposits 300 eggs of females, and as many of males. The elder brothers, or first-hatched insects, take amazing care of those born after them, by proportioning their food to the delicacy of their stomach. First, it consists of the juice of fruits and meats; afterwards it is the carcases of insects. The caterers provide for the labourers. Each one takes his own portion; there is no dispute, no fighting. The republic grows daily more numerous, living in profound peace. Every individual, as soon as he has acquired sufficient strength, flies away to the fields. They then become a gang of banditti; they pillage our wall-trees, break into our fruit before its maturity, dart with the fierceness of hawks upon our bees, cut their throats to possess themselves of their honey, plunder and lay waste their commonwealth, riot on the fruits of their labour, and oblige them to remove. During the period of plenty, the wasps bring all the booty to the nest, and share it amongst them. There is nothing then goes forwards but feasting, rioting, and good fellowship; but concord

cannot be lasting among robbers. Towards the month of October, provisions begin to run short; when this lively, this amiable young brood is fired with a kind of rage, and the nest is now nothing but a scene of horror. The neuters and males tear from their cradles the eggs, the larvæ, the chrysalids, and the new-born insects, without showing mercy to any. They next fight against one another; tho' their duels seldom proceed to death as those do of the bees. The males alone are destitute of stings. The hopes of the state, the solicitude for posterity, the love of their native place, no longer exist; the whole commonwealth is overturned to the very foundation. Frosts and rains throw the citizens into a state of languor. They almost all perish; luckily for us and our bees. Some few females escape the disasters of intestine war, and the severity of winter, which in the ensuing spring become founders of new republics. One robber is sometimes useful in bringing another to punishment. Some butchers hang up before their shop a calf's liver, or any other tender meat. The wasps come in quest of this delicate food; and, fond of enjoying it to themselves, they pursue the blue-bottle flies from whose eggs are produced the maggots that spoil meat; and this is the only advantage we can reap from wasps.

Aërial wasps are the smallest species of them; nor is their society numerous. Their history, as well as their manners, are the same as those of the common wasp; but their buildings are on a different construction. Their nest is fastened to the branch of a tree with a kind of band; and is in bigness from the size of an orange down to that of an egg. Wood reduced to paper is the material part of it; which if it were of a ruddy colour, might be taken for a large opening rose. It is covered over with a varnish impenetrable by water. One of those nests was neither mollified nor impaired by that element.

VESPASIAN, the 10th emperor of Rome; remarkable for his clemency and other virtues. See *ROME*, n° 332—339.

VESPER, in the church of Rome, denote the afternoon service; answering in some measure to the evening prayers of the church of England.

VESPERTILIO, the BAT; a genus of quadrupeds, belonging to the order of primates. All the teeth are erect, pointed, near each other; and the first four are equal. The fore-feet have the toes connected by a membrane expanded into a kind of wings, by which the creature is enabled to fly. There are many species; of which the most remarkable are,

1. The vampyrus, vampire, or Ternate bat, with large canine teeth; four cutting teeth above, the same below; sharp black nose; large naked ears; the tongue is pointed, terminated by sharp aculeated papillæ; talons very crooked, strong, and compressed sidewise; no tail: the membrane divided behind quite to the rump: head of a dark ferruginous colour; on the neck, shoulder, and under-side, of a much lighter and brighter red; on the back the hair shorter, dusky, and smooth: the membranes of the wings dusky. They vary in colour; some being entirely of a reddish brown, others dusky.

These monsters inhabit Guinea, Madagascar, and all the islands from thence to the remotest in the Indian Ocean. They fly in flocks, and perfectly obscure the

Vespa

Vespertilio.

Vespertilio. air with their numbers; they begin their flight from one neighbouring island to another immediately on sunset, and return in clouds from the time it is light till sun-rise. They live on fruits; and are so fond of the juice of the palm-tree, that they will intoxicate themselves with it till they drop on the ground. It is most likely, from the size of their teeth, they are carnivorous. Mr Edwards relates, that they will dip into the sea for fish. They swarm like bees; hanging by one another from the trees in great clusters. The Indians eat them, and declare the flesh to be very good: they grow excessively fat at certain times of the year. The French who live in the *Île de Bourbon*, boil them in their bouillon, to give it a relish. The negroes have them in abhorrence. Many are of an enormous size: Beckman measured one, whose extent from tip to tip of the wings was five feet four inches; and Dampier another, which extended further than he could reach with out-stretched arms. Their bodies are from the size of a pullet to that of a dove: their cry is dreadful, their smell rank, their bite, resistance, and fierceness great, when taken.

The ancients had some knowledge of these animals. Herodotus mentions certain winged wild beasts like bats, that molested the Arabs who collected the cassia, to such a degree, that they were obliged to cover their faces, all but their eyes, with skins. It is very probable, as M. de Buffon remarks, it was from such relations that poets formed their fictions of Harpies.

Linnaeus gives this species the title of *vampyre*; conjecturing it to be the kind which draws blood from people in their sleep. M. de Buffon denies it; ascribing that faculty only to a species found in South America. But there is reason to imagine that this thirst after blood is not confined to the bats of one continent, nor to one species: for Bontius and Nieuhoff informs us, that the bats of Java seldom fail attacking persons who lie with their feet uncovered, whenever they can get access; and Gumilla, after mentioning a greater and lesser species found on the banks of the *Oronoque*, declares them to be equally greedy after human blood. Persons thus attacked have been known to be near passing from a sound sleep into eternity. The bat is so dexterous a bleeder, as to insinuate its aculeated tongue into a vein without being perceived, and then suck the blood till it is satiated; all the while fanning with its wings, and agitating the air in that hot climate in so pleasing a manner, as to lull the sufferer into a still sounder sleep. It is therefore very unsafe to rest either in the open air, or to leave open any entrance to these dangerous animals: but they do not confine themselves to human blood; for M. Condaminé says, that in certain parts of America they have destroyed all the great cattle introduced there by the missionaries.

2. The *Spixtrum*, or *spixtre*, with a long nose; large teeth; long, broad, and upright ears; at the end of the nose a long conic erect membrane, bending at the end, and flexible: hair on the body cinerous, and pretty long: wings full of ramified fibres: the membrane extends from hind leg to hind leg; no tail; but from the rump extend three tendons, terminating at the edge of the membrane. By Seba's figure the extent of the wings are two feet two inches; from the end of the nose to the rump, seven inches and an half.

Inhabits South America; lives in the palm-trees;

grows very fat; called *vampyre* by M. de Buffon, who supposes it to be the species that sucks human blood: but neither Piso, nor any other writer who mentions the fact, gives the least description of the kind.

3. The Peruvian bat hath a head like a pug-dog; large straight-pointed ears; two canine teeth, and two small cutting teeth between each, in each jaw: the tail is inclosed in the membrane which joins to each hind-leg, and is also supported by two long cartilaginous ligaments involved in the membrane: colour of the fur, iron grey: body equal to that of a middle-sized rat: extent of wings two feet five inches.

4. The noctule hath the nose slightly bilobated; ears small and rounded; on the chin a minute verruca; hair reddish ash-colour: length of the rump two inches eight-tenths; tail one inch seven-tenths; extent of wings 13 inches. Inhabits Great Britain and France; flies high in search of food, not skimming near the ground. A gentleman informed Mr Pennant of the following fact relating to those animals, which he was witness to: That he saw taken under the eaves of Queen's College, Cambridge, in one night, 185; the second night, 63; the third night, 2; and that each that was measured had 15 inches extent of wings.

Bats appear abroad in this country early in the spring; sometimes they are tempted by a warm day to fall out in the winter. They fly in the evenings, and live on moths and other nocturnal insects. They fly by jerks, not with the regular motion of birds, for which the ancients mistook them. They frequent glades and shady places: will go into larders, and gnaw any meat they find. They bring two young at a time, which they suckle at their breast. They retire at the end of summer into caves, the caves of houses, and into ruined buildings, in vast multitudes, where they generally remain torpid, suspended by the hind-legs, enveloped in their wings. They are the prey of owls. Their voice is weak. Ovid takes notice both of that and the origin of the Latin name:

*Minimum pro corpore vocem
Emitunt; peraqueque levis stridore querelas.
Tætaque, non silvas celebrant; lucenque perosa
Noctæ volant: siroque trahunt a vespere nomen.*

VESSEL, a general name given to the different sorts of ships which are navigated on the ocean, or in canals and rivers. It is, however, more particularly applied to those of the smaller kind, furnished with one or two masts. See *SHIP*; and Plate CCLXIV. and CCLXV.

VESTA, in pagan worship, the same with Cybele. See *CYBELE*.

VESTA the *Younger*, in pagan worship, the goddess of Fire, was the daughter of Saturn and Cybele, and the sister of Ceres. She was so much in love with chastity, that on Jupiter's ascending the throne and offering to grant whatever she asked, she only desired the preservation of her virginity, which she obtained.—Vesta was not represented in her temple by any image.

VESTALIA, in Roman antiquity, a festival celebrated in honour of the goddess Vesta, on the 5th of the ides of June; that is, on the ninth of the month.

VESTALS, among the ancient Romans, were priestesses of the goddess Vesta, and had the perpetual fire committed to their charge: they were at first only four in number, but afterwards increased to six; and it does

Vespertilio
||
Vestals.

does not appear that their number ever exceeded six, among whom was one superior to the rest, and called *vestalis maxima*.

The vestals were chosen from six to ten years of age, and obliged to strict continency for 30 years; the first 10 of which were employed in learning the ceremonies of religion, the next 10 in the performance of them, and the 10 last in teaching them to the younger vestals.

The habit of the vestals consisted of an head-dress, called *infula*, which sat close to the head, and from whence hung certain laces called *vitæ*; a kind of surplice made of white linen, and over it a purple mantle with a long train to it.

VESTIBLE, in architecture, a kind of entrance into a large building; being an open place before the hall, or at the bottom of the stair-case.

VESTRY, a place adjoining to a church, where the vestments of the minister are kept; and also a meeting at such place, consisting of the minister, church-wardens, and chief men of most parishes, who make a parish vestry or meeting. By custom there are select vestries, being a certain number of persons chosen to have the government of the parish, make rates, and take the accounts of church-wardens, &c.

VESUVIUS, a famous burning mountain situated six miles east from the city of Naples in Italy.

One side of this volcano is well cultivated and fertile, producing great plenty of vines; but the south and west sides are entirely covered with cinders and ashes; while from the top a sulphureous smoke, and sometimes most violent flames, &c. as in other volcanoes. From the foot of the mountain to the top is about three Italian miles, but the perpendicular height is only 3700 feet. The ascent on these sides, by reason of the steepness of the mount, is very difficult and tedious; but there are some peasants who live about the mountain, and for a small consideration assist travellers in clambering up. They wear leathern belts, of which the strangers take hold in order to render their ascent more easy. The mountain has two tops, one of which only is properly called *Vesuvius*: the other goes by the name of *Somma*; and Sir William Hamilton is of opinion that it is the latter which the ancients called *Vesuvius*.

The first remarkable eruption of *Vesuvius* happened in the year 79, in the reign of the emperor Titus, when the cities of Pompeii and Herculaneum were entirely buried by the stones and ashes thrown out. Incredible mischief also was done to the neighbouring country, and numbers of people lost their lives, among whom was Pliny the Elder, whose curiosity having induced him to approach too near, he was suffocated by the noxious steams. This eruption appears to have been very violent; but though it is the first on record, it is the opinion of the best judges, that it was by no means the first which had happened. Since that time, however, they have been much more frequent, and we have accounts of 29 different eruptions. Of these a very remarkable one happened in 1767; of which some particulars are related under the article *Ætna*, for the sake of illustrating the history of that mountain. But by far the most remarkable which is recorded either of *Vesuvius* or any other mountain, happened in the year 1779, and is particularly related by Sir William Hamilton in the Philosophical

Transactions for 1780; to which we beg leave to refer the reader, as the detail would be here improper after the full account given of volcanic phenomena under the article above-mentioned. See also *VOLCANO*.

VETCH, in botany. See *VICIA*.

VETERAN, among the ancient Romans, an appellation given to a *solatier* grown old in the service, or who had made a certain number of campaigns.

VEXILLUM, in botany; the upper petal of a pea-bloom, or butterfly-shaped flower, which is generally larger than any of the others.

VIALES, in mythology, a name given among the Romans to the gods who had the care and guard of the roads and high-ways.

VIATICUM, in Roman antiquity, an appellation given in common to all officers or any of the magistrates; as *littors*, *accessit*, *scribes*, *criers*.

VIBEX, is sometimes used, by physicians, for a black and blue spot in the skin occasioned by an afflux or extravasation of blood.

VIBRATION, in mechanics, a regular, reciprocal motion of a body, as a pendulum,

VIBURNUM, in botany, a genus of the trigynia order, belonging to the pentandria class of plants. There are nine species, of which the most remarkable are, 1. The *lantana*, common *viburnum*, wayfaring, or plant mealy tree, rises with a woody stem, branching twenty feet high, having very pliant shoots covered with a lightish-brown bark; large heart-shaped, veined, serrated leaves, white and hoary underneath; and the branches terminated by umbels of white flowers, succeeded by bunches of red berries. It grows naturally in England in hedges, &c. 2. The *opulus*, or *gelderrose*; consisting of two varieties, one with flat-flowers, the other globular. The former grows eighteen or twenty feet high, branching opposite, of an irregular growth, and covered with a whitish bark; large lobed or three-lobed leaves on glandulose foot-stalks, and large flat umbels of white flowers at the ends of the branches, succeeded by red berries. Grows naturally in England in marshy places. The latter grows fifteen or eighteen feet high, branching like the other, garnished with large lobed or three-lobed leaves, on glandular foot-stalks; and large globular umbels of white flowers at the ends of the branches, in great abundance. This tree when in bloom exhibits a singularly fine appearance: the flowers, though small, are collected numerously into large globular umbels round like a ball; hence, it is sometimes called *snowball-tree*. 3. The *tinus*, common *laurostinus*, or *evergreen viburnum*; grows eight or ten feet high or more, branching numerously from the bottom upwards, assuming a close bushy growth, with the branches somewhat hairy and glandulous; very closely garnished with oval, wholly entire leaves, of a strong green colour, placed in pairs opposite; and whitish and red flowers, collected numerously in large umbellate clusters all over the plant, at the sides and ends of the branches, from January until March or April, exhibiting a most beautiful appearance. There are a great many varieties; narrow-leaved—broad-leaved—shining-leaved—hairy-leaved—white-striped leaved—yellow-striped leaved; all of which are of shrubby, bushy growth, closely garnished with leaves all the year, and producing a great profusion of

Vicar
||
Victor.

umbellate flowers in winter and spring. All the different species of viburnum, both deciduous and evergreen kinds, being of the tree kind, are woody and durable in root, stem, and branches. They may all be propagated by layers; and are of such hardy temperature, as to grow freely in the open ground all the year, in shrubberies, and other hardy plantations.

VICAR, a person appointed as deputy to another, to perform his functions in his absence, and under his authority.

VICAR, in the canon-law, denotes a priest of a parish, the predial tithes whereof are impropriated or appropriated; that is, belong either to a chapter, religious house, &c. or to a layman who receives them, and only allows the vicar the small tithes, or a convenient salary. See the article PARSON and Vicar.

VICE, in ethics, is ordinarily defined an elective habit, denoting either an excess or defect from the just medium wherein virtue is placed.

VICE, in smithery and other arts conversant in metals, a machine or instrument serving to hold fast any thing they are at work upon, whether it is to be beat, filed, or rivetted.

VICE is also used in the composition of divers words to denote the relation of something that comes instead or in the place of another; as vice-admiral, vice-chancellor, &c. are officers who take place in the absence of admirals, &c.

VICEROY, a governor of a kingdom, who commands in the name and instead of a king, with full and sovereign authority. See KING.

VICIA, the TARE or VETCH; a genus of the decandria order, belonging to the diadelphia class of plants. There are 18 species, the most remarkable of which is the fativa or common tare. This is so well known, that no description needs be given. It is known to be an excellent fodder for horses. In some parts of England the crop is ploughed in to answer the purposes of manure to the land. Pigeons are very fond of the seeds; and in some parts of Sweden, &c. they enter into the composition of bread, either alone, or mixed with the flour of rye.—A decoction of them in water is sometimes given by the common people in England to expel the small-pox and measles.

VICISSITUDE, the regular succession of one thing after another; as the vicissitude of day and night, of the seasons, &c.

VICTIM, denotes a bloody sacrifice offered to some deity, of a living creature, as a man or beast, which is slain to appease his wrath, or obtain some favour.

VICTOR (Sextus Aurelius), a Roman historian, who flourished under the emperors Constantine and Julian; as we learn from many passages in his own writings, and also from Ammianus Marcellinus. This historian relates, that Constantine made him consul, and honoured him with a brazen statue, on account of his excellent qualifications; although, as he owns of himself, he was born in an obscure village, and of poor and illiterate parents. It is commonly believed that he was an African: it is certain, that he dwells much upon the praises of that country, which he calls the glory of the earth; *decus terrarum*. Two books of his are extant in the historical way: one *De viris*

illustris urbis Romæ; the other, *De Cæsaribus*; to which is prefixed *Libellus de origine gentis Romanæ*. The whole makes an abridged history of Rome, from its foundation down to the reign of Julian inclusive.

VICTORY, the overthrow or defeat of an enemy in war or combat.

VICTORY, in pagan worship, is represented by Hefiod as the daughter of Siyx and Pallas; and Varro calls her the daughter of Heaven and Earth. The Romans erected a temple to her, where they prayed to the gods to give success to their arms. They painted her in the form of a woman, clad in cloth of gold. In some medals, she is represented with wings flying through the air, holding a laurel crown in one hand and a palm in the other; but in other medals, she is seen standing upon a globe, with the same crown and branch of palm.

VIDA (Marcus Hieronymus), bishop of Alva, in Mountferrat, and one of the most excellent Latin poets that have appeared since the Augustan age, was born at Cremona in 1470. Having distinguished himself by his learning, and taste for literature, he was made bishop of Alva in 1552. After continuing two years with pope Clement VII. at Rome, he went to reside upon his see; where, for 30 years, he performed all the offices of a good bishop and a good man; and though he was mild, gentle, and full of goodness, he was so far from wanting spirit, that when the city of Alva was besieged by the Gauls, he used all possible means to prevent its being given up, by strenuously exhorting the people, and, when provisions were scarce, by supplying them at his own expence. His poetics, and poem on the silk-worm, pass for his masterpiece; his poem on the game of chess is also greatly admired. He also wrote hymns, bucolics, eclogues, and a poem entitled *Christiadas* in six books; all which are in Latin, and have gained him a great reputation. His works in prose consist of dialogues, synodical constitutions, letters, and other pieces. He died in 1566, soon after his being made bishop of Cremona.

VIENNA, a large and celebrated city of Germany, in the circle of Austria, and capital of the Hungarian dominions. It stands on the south side of the Danube, 40 miles west of Presburg, 40 east of Lintz, 100 north-west of Buda, 180 south-west of Cracow, 450 north of Rome, 560 east of Rotterdam, 500 from Paris, 600 from London, and 570 west of Constantinople. The Turks call it *Beez*, the natives *Wien*, and the Poles *Wieden*. The ancient Vindobona stood in the neighbourhood. The Danube is here pretty wide, forming several beautiful islands well stocked with woods. The country to the east and north is level; but to the west and south there is a range of mountains, clothed with trees and vines. It seems to have been a considerable place in the time of the Romans: for it was the station of their Classis Africa, or navy on the Danube; and here the emperor Marcus Aurelius is said to have died. In 1192 it was enlarged, beautified, and walled round, with the ransom-money which the marquis of Austria obliged Rich. I. of England to pay when he made him prisoner in his return from the Holy Land, because he took down the Austrian banner at Joppa, and threw it into the house of office. The city itself is of no great extent, contain-

Victory
||
Vienna

containing, besides churches and cloisters which have generally extensive gardens and walks, about 1200 houses from four to seven stories high, 80 streets, and 15 principal squares. There are many magnificent palaces in it; and in the burghers houses the second story is allotted for the residence of the imperial court officers. It is well fortified after the modern way; and, including the suburbs, may be about a quarter as big as London and Westminster. It is very populous, having always great numbers of strangers in it, of most European nations, in their proper habits, and may contain generally about 180,000 souls. The streets are narrow and dirty; and the air would be very unwholesome, were it not for the high winds which blow here most part of the year: whence the proverb, *Vienna vel ventosa, vel venenosa*. In most of the squares are beautiful fountains and magnificent monuments, erected by the emperors. The metropolitan church of St Stephen is a large magnificent Gothic building, with a tower 460 Austrian feet high, and a bell upwards of 10 feet in height and 32 in circumference. The bowels of the archducal family at their deaths are deposited in a vault of this church; but their hearts in the cloister church of the bare-footed Augustines, which is the imperial abbey-church, and their bodies in that of the capuchin-cloister. The archbishop's revenue is near 30,000 imperial florins per annum. Among the cloisters, of which there are a great number here, both in the city and suburbs, one of the principal is the Schotten, or Scottish Benedictine abbey, whose abbot is mitred, and to whose jurisdiction the populous suburb of St Ulrich, together with the Neubau, is subject. This abbey was founded for the Scots, in honour of their countryman St Colman, who was formerly reckoned the patron of Austria. At the entrance of St Stephen there is a stone placed in the wall, and held in great veneration by the Papists, being supposed to be one of those with which St Stephen was stoned to death. It looks like a pebble, and is worn very smooth, in consequence of the superstition of the people, who are continually touching it out of devotion. From the spire of the church is a most noble prospect of the city and adjacent country, and of the Danube, almost to Presburgh in Hungary. In the tower there is a case of wooden hammers, with which they call the people to church from Good-Friday to Easter-Sunday, because they will not suffer the bells to ring out during the time that our Saviour is supposed to have lain in the grave. Here are many hospitals; one in particular called the *Burgher-spital*, in which near 3000 persons are maintained. The imperial palace is a mean old building, consisting of two courts; the inner for the imperial family; and the outer, which is the largest, for lodging the courtiers and guards. The imperial cabinet of coins and medals is the largest and grandest in Europe; and the imperial library equals, if not exceeds, that of the Vatican, and the royal library at Paris, being supposed to contain near 100,000 volumes. Among other curious manuscripts is one of Livy, above 1000 years old; a Greek manuscript of Dioscorides, above 1100; a Greek manuscript of the book of Genesis above 1300, containing many curious draughts and representations in miniature or water-colours; Luther's Bible, with a great many notes in his own hand-writing; a

Greek manuscript of the New Testament, above 1500 years old, in gold letters on purple. Here is a noble university, endowed with large revenues and privileges; and divided into four classes, having each of them peculiar rules and immunities; namely, the Austrian class for the students of Austria, Italy, and other countries beyond the Alps; that of the Rhine, for the western parts of the empire, France, Spain, and the Netherlands; that of the Hungarians, for Hungary, Bohemia, with other countries, which speak Slavonic, and some parts of Germany, with Great Britain and Ireland. The principal, or chancellor, with the other masters of the university, have the power of life and death over the scholars: but the establishments for painting, sculpture, and the other fine arts, are on a much better footing here than those for the sciences, especially in respect to philosophy and divinity, which are little better than a heap of scholastic chimeras. However, in the year 1752, an imperial ordinance was issued, with a view to improve the method of teaching. Vienna is divided into four quarters, one of which is called the *Schotten*, that is, the Scots quarter. One of the gates also is called the *Scots gate*, in remembrance of some noble exploit performed there by the troops of that nation. The ministers of the Protestant crowned heads have chapels here, as in other Roman Catholic countries; and some Protestants held offices, both civil and military, under the late emperor Charles VI. The suburbs are much larger than the city itself. To ride round the line which incloses them, at an ordinary pace, would take up about four hours. The largest of them is called *Leopold stadt*, from the emperor Leopold. In that of Rouslau, is the grand palace of Lichtenstein. In that of Wieden, is the new imperial favourite, or summer-palace. In that called *Rennweg*, is the cloister of the female Salesians or English nuns, with the grand palaces of the late prince Eugene of Savoy, and of the prince of Schwarzenberg. In that called *Landstrasse*, is a fine cloister of hermits of the order of St Augustine, who wear white ermine. The city, by means of the Danube, is well supplied with provisions, and everything else useful, necessary, or agreeable. As it is the seat of the court, and the supreme colleges and tribunals, there is a prodigious resort to it, especially of the noblesse, from all the hereditary countries, and others, particularly those of the empire. The grandeur of this court exceeds that of most others. All or most of the officers of state and of the household, of the horse and foot guards, and above 100 gentlemen of the bed-chamber, who wear golden keys at their breasts, are either princes, counts, or barons; but the etiquette, that is, ancient forms and usages which are rigidly observed, though universally exclaimed against, gives it an air of constraint, that is no where else to be seen. Days of Gala, i. e. festivals and holidays, are very welcome to both the court and city. They are of three sorts, the court-gala, the grand-gala, and little-gala. The first are the birth-days, name-days, &c. of the emperor and empress. The second, those of some minister, which are kept in the city. And the third, when any piece of good fortune happens to a family of rank and distinction.

VIGIL, in church-history, is the eve or next day before any solemn feast; because then Christians were

Vigl's. wont to watch, fast, and pray, in their churches.

VIGILS of Plants, a term under which botanists comprehend the precise time of the day in which the flowers of different plants open, expand, and shut.

As all plants do not flower in the same season, or month; in like manner, those which flower the same day, in the same place, do not open and shut precisely at the same hour. Some open in the morning, as the lily flowers, and compound flowers with flat spreading petals; others at noon, as the mallows; and a third set in the evening, or after sun-set, as some geraniums and opuntias: the hour of shutting is equally determined. Of those which open in the morning, some shut soon after, while others remain expanded till night.

The hours of opening, like the time of flowering, seem to vary, according to the species of the plant, the temperature of the climate, and that of the season. Flowers, whose extreme delicacy would be hurt by the strong impressions of an ardent sun, do not open till night; those which require a moderate degree of heat to elevate their juices, in other words, whose juices do not rise but in the morning or evening, do not expand till then; whilst those which need a more lively heat for the same purpose, expand at noon, when the sun is in his meridian strength. Hence it is, that the heat of the air being greater betwixt the tropics than elsewhere, plants which are transported from those climates into the cold or temperate climates of Europe, expand their flowers much later than in their native soil. Thus, a flower which opens in summer at six o'clock in the morning at Senegal, will not open at the same season in France and England till eight or nine, nor in Sweden till ten; that which opens at ten at Senegal, does not open in France and England till noon; and, in Sweden, the plant does not flower, or, at least, loses its petals, and frequently bears no fruit: lastly, a plant which opens its flowers, in Senegal, at noon, or at one or two hours after noon, bears neither flowers nor fruit in France, England, and Sweden. The same thing happens to most plants of temperate countries, when removed to Senegal, or other sultry climes.

Linnaeus distinguishes by the general name of *solar* (*flores solares*) all those flowers which observe a determinate time in opening and shutting. These flowers are again divided, from certain circumstances, into three species, or kinds:

Equinoctial flowers (*flores aequinoctiales*) are such as open and shut at all seasons, at a certain fixed or determinate hour.

Tropical flowers (*flores tropici*) are such whose hour of opening is not fixed at all seasons, but accelerated or retarded according as the length of the day is increased or diminished.

Meteorous flowers (*flores meteorici*) are such whose hour of expansion depends upon the dry or humid state of the air, and the greater or less pressure of the atmosphere. Of this kind is the Siberian fow-thistle, which shuts at night if the ensuing day is to be clear and serene, and opens if it is to be cloudy and rainy. In like manner the African marigold, which in dry serene weather opens at six or seven in the morning, and shuts at four o'clock in the afternoon, is a sure indication that rain will fall during the course of the day, when it continues shut after seven.

VIGNOLA (James Barozzio de), a learned architect of the 16th century, was born at Vignola a small town in the marquise of that name, and became esteemed at Rome and in France for his taste and skill in the art of building and casting statues. He composed a book on the five orders of architecture, which is esteemed; and died at Rome in 1573, aged 66.

VIGO, a sea-port town of Spain, in Galicia, with an old castle and a fort. It is seated in a fertile country by the sea-side. It was rendered famous by a sea-fight between the confederate fleet commanded by Sir Geo. Rooke, and a squadron of French men of war, while the duke of Ormond with a body of land-forces drove the Spaniards from the castles which defended the harbour. Admiral Hopson having with infinite danger, broke thro' the boom, made across the mouth of the harbour, the English took four galleons and five large men of war, and the Dutch five galleons and one man of war. Four galleons, with 14 men of war, were destroyed, with abundance of plate and other rich effects. W. Long. 8. 21. N. Lat. 42. 3.

VILLA FRANCA, the name of several towns; one in Piedmont, three miles east of Nice; another of Catalonia, 18 miles west of Barcelona; a third, the capital of St Michael, one of the Azores; and a fourth, a town of Eltreadura in Spain, 57 miles south-east of Salamanca.

VILLAGE, an assemblage of houses inhabited chiefly by peasants and farmers, and having no market, whereby it is distinguished from a town. The word is French, formed of *vil*, or *villis*, "low, mean, contemptible;" or rather, from the Latin *villa*, a country-house or farm.

VILLAIN, or **VILLEIN**, in our ancient customs, denotes a man of servile or base condition, viz. a bondman or servant.

VILLARS (Lewis Hector, duke de) marshal of France, grandee of Spain, &c. and a very brave general in the 18th century, was the son of Peter marquis de Villars, of a noble and ancient family. He was at first aid-de camp to marshal de Bellefons, his cousin; and distinguished himself in several sieges and battles till the year 1702, when having obtained the victory at Fredlinghem from the prince of Baden, he was made marshal of France. The marshal de Villars took the fort of Kell the year following, and gained the battle of Hochstet. In 1707 he forced the lines of Stolhoffen, and raised large contributions from the enemy: but in 1709, he, in conjunction with marshal Boufflers, was entirely defeated by the duke of Marlborough, at the battle of Malplaquet, when marshal Villars was wounded at the beginning of the action. In 1712, he gained much glory by forcing the intrenchments at Denain on the Scheld; which was followed by the taking of Marchiennes, Douay, Bouchain, Landau, Friburg, &c. and by the peace concluded at Rastat between the emperor and France in 1714. The marshal de Villars, who had been plenipotentiary at the treaty of Rastat, was made president of the council of war in 1715, then counsellor of the regency, and minister of state. In 1733, he was nominated to command in Italy under the king of Sardinia, and the French king declared him marshal-general of his camps and armies; a title which had not been granted to any one since the marshal Turenne, who

Villanage. who appears to have been the first who was ever honoured with it. The marshal de Villars made himself master of P.ighitona, Milan, Novare, and Tortona. But having opened the following campaign, he fell sick, and died at Turin, in 1734, aged 82. The Memoirs of M. de Villars have been published in Holland, the first volume of which was written by himself.

VILLENAGE, in law. The folk-land or estates held in villanage, was a species of tenure neither strictly feudal, Norman, or Saxon; but mixed, and compounded of them all; and which also, on account of the heriots that usually attend it, may seem to have somewhat Danish in its composition. Under the Saxon government there were, as Sir William Temple speaks, a sort of people in a condition of downright servitude, used and employed in the most servile works, and belonging, both they, their children, and effects, to the lord of the soil, like the rest of the cattle or flock upon it. These seem to have been those who held what was called the *fólkland*, from which they were removeable at the lord's pleasure. On the arrival of the Normans here, villeins seem improbable, that they, who were strangers to any other than a feudal state, might give some sparks of enfranchisement to such wretched persons as fell to their share, by admitting them, as well as others, to the oath of fealty; which conferred a right of protection, and raised the tenant to a kind of estate superior to downright slavery, but inferior to every other condition. This they called *villanage*, and the tenants *villeins*, either from the word *villus*, or else, as Sir Edward Coke tells us, from *villa*; because they lived chiefly in villages, and were employed in rustic works of the most lordly kind: like the Spartan *hektes*, to whom alone the culture of the lands was confided; their rugged masters, like our northern ancestors, esteeming war the only honourable employment of mankind.

These villeins, belonging principally to lords of manors, were either villeins *regardant*, that is, annexed to the manor or land: or else they were *in gross*, or at large; that is, annexed to the person of the lord, and transferable by deed from one owner to another. They could not leave their lord without his permission; but, if they ran away, or were purloined from him, might be claimed and recovered by action, like beasts or other chattels. They held indeed small portions of land by way of sustaining themselves and families; but it was at the mere will of the lord, who might dispossess them whenever he pleased; and it was upon villein services, that is, to carry out dung, to hedge and ditch the lord's demesnes, and any other the meanest offices: and their services were not only bad, but uncertain both as to their time and quantity.

A villein could acquire no property either in lands or goods: but, if he purchased either, the lord might enter upon them, oust the villein, and seize them to his own use; unless he contrived to dispose of them again before the lord had seized them, for the lord had then lost his opportunity.

In many places also a fine was payable to the lord, if the villein presumed to marry his daughter to any one without leave from the lord: and, by the common law, the lord might also bring an action against the husband for damages in thus purloining his property.

Villanage. For the children of villeins were also in the same state of bondage with their parents; whence they were called in Latin, *nativij*, which gave rise to the female appellation of a villein, who was called a *neise*. In case of a marriage between a freeman and a neise, or a villein and a freewoman, the issue followed the condition of the father, being free if he was free, and villein if he was villein; contrary to the maxim of the civil law, that *partus sequitur ventrem*. But no bastard could be born a villein, because by another maxim of our law he is *nullius filius*; and as he can gain nothing by inheritance, it were hard that he should lose his natural freedom by it. The law, however, protected the persons of villeins, as the king's subjects, against atrocious injuries of the lord: for he might not kill or maim his villein; though he might beat him with impunity, since the villein had no action or remedy at law against his lord, but in case of the murder of his ancestor or the maim of his own person. Neise indeed had also an appeal of rape, in case the lord had violated them by force.

Villeins might be enfranchised by manumission. In process of time they gained considerable ground on their lords; and in particular strengthened the tenure of their estates to that degree, that they came to have in them an interest in many places full as good, in others better than their lords. For the good-nature and benevolence of many lords of manors having, time out of mind, permitted their villeins and their children to enjoy their possessions without interruption, in a regular course of descent, the common law, of which custom is the life, now gave them title to prescribe against their lords; and, on performance of the same services, to hold their lands, in spite of any determination of the lord's will. For, though in general they are still paid to hold their estates at the will of the lord, yet it is such a will as is agreeable to the custom of the manor; which customs are preserved and evidenced by the rolls of the several courts-baron in which they are entered, or kept on foot by the constant immemorial usage of the several manors in which the lands lie. And, as such tenants had nothing to show for their estates but these customs, and admissions in pursuance of them, entered on those rolls, or the copies of such entries witnessed by the steward, they now began to be called *tenants by copy of court-roll*, and their tenure itself a *copyhold*.

Privileged VILLENAGE, a species of tenure otherwise called *villein-sage*. See **TENURE**.

Ancient demesne consists of those lands or manors which, though now perhaps granted out to private subjects, were actually in the hands of the crown in the time of Edward the confessor, or William the conqueror; and so appear to have been by the great survey in the exchequer called *demefay book*. The tenants of these lands, under the crown, were not all of the same order or degree. Some of them, as Britton testifies, continued for a long time pure and absolute villeins; dependent on the will of the lord: and common copyholders in only a few points. Others were in great measure enfranchised by the royal favour: being only bound in respect of their lands to perform some of the better sort of villein-services; but those determinate and certain; as, to plough the king's land for so many days, to supply his court with

such

such a quantity of provisions, and the like; all of which are now changed into pecuniary rents: and in consideration hereof they had many immunities and privileges granted to them; as, to try the right of their property in a peculiar court of their own, called a *court of ancient demesne*, by a peculiar process denominated a writ of right close: not to pay toll or taxes; not to contribute to the expenses of knights of the shire; not to be put on juries, and the like.

These tenants therefore, though their tenure be absolutely copyhold, yet have an interest equivalent to a freehold: for, though their services were of a base and villainous original, yet the tenants were esteemed in all other respects to be highly privileged villeins; and especially for that their services were fixed and determinate, and that they could not be compelled (like pure villeins) to relinquish those tenements at the lord's will, or to hold them against their own: *et ideo*, says Bracton, *dicuntur liberi*.

Lands holding by this tenure are therefore a species of copyhold, and as such preserved and exempted from the operation of the statute of Charles II. Yet they differ from common copyholds, principally in the privileges before-mentioned: as also they differ from freeholders by one especial mark and tincture of villenage, noted by Bracton, and remaining to this day; viz. that they cannot be conveyed from man to man by the general common law conveyances of feoffment, and the rest; but must pass by surrender to the lord or his steward, in the manner of common copyholds: yet with this difference, that, in the surrenders of these lands in ancient demesne, it is not used to say, "to hold at the will of the lord," in their copies; but only, "to hold according to the custom of the manor."

VILLI, among botanists, a kind of down like short hair, with which some trees abound.

VILLIERS (George duke of Buckingham), an ingenious and witty nobleman, whose mingled character rendered him at once the ornament and disgrace, the envy and ridicule, of the court he lived in, was son to that famous statesman and favourite of king Charles I. who lost his life by the hands of Lieutenant Felton. He was born in 1627, the year before the fatal catastrophe of his father's death. The early parts of his education he received from various domestic tutors, after which he was sent to the university of Cambridge. Having here completed a course of studies, he, with his brother Lord Francis, went abroad under the care of one Mr Aylebury.—Upon his return, which was not till after the breaking out of the civil wars, the king being at Oxford, his grace repaired thither, was presented to his majesty, and entered of Christ-church college. Upon the decline of the king's cause, he attended prince Charles into Scotland, and was with him at the battle of Worcester in 1661; after which, making his escape beyond sea, he again joined him, and was soon after, as a reward for this attachment, made knight of the garter.

Desirous, however, of retrieving his affairs, he came privately to England; and in 1657 married Mary, the daughter and sole heiress of Thomas lord Fairfax, through whose interest he recovered the greatest part of the estate he had lost, and the assurance of succeeding to an accumulation of wealth in the right of his wife.

We do not find, however, that this step lost him the royal favour; for after the restoration, at which time he is said to have possessed an estate of L. 20,000 *per annum*, he was made one of the lords of the bed-chamber, called to the privy-council, and appointed lord lieutenant of Yorkshire and master of the horse. All these high posts, however, he lost again in the year 1666. For having been refused the post of president of the north, he became disaffected to the king; and it was discovered that he had carried on a secret correspondence by letters and other transactions with one Dr Heydon, tending to raise mutinies among his majesty's forces, particularly in the navy, to stir up sedition among the people, and even to engage persons in a conspiracy for the seizing the tower of London. Matters were ripe for execution; and an insurrection, at the head of which the duke was openly to have appeared, was on the very eve of breaking out, when it was discovered by means of some agents whom Heydon had employed to carry letters to the duke. The detection of this affair so exasperated the king, who knew Buckingham to be capable of the blackest designs, that he immediately ordered him to be seized; but the duke finding means, having defended his house for some time by force, to make his escape, his majesty struck him out of all his commissions, and issued a proclamation requiring his surrender by a certain day.

This storm, however, did not long hang over his head; for, on his making an humble submission, king Charles, who was far from being of an implacable temper, took him again into favour, and the very next year restored him both to the privy-council and bed-chamber. But the duke's disposition for intrigue and machination could not long lie idle; for having conceived a resentment against the duke of Ormond for having acted with some severity against him in regard to the last-mentioned affair, he, in 1670, was supposed to be concerned in an attempt made on that nobleman's life by the same Blood who afterwards endeavoured to steal the crown. Their design was to have conveyed the duke to Tyburn, and there to have hanged him; and so far did they proceed towards the putting it in execution, that Blood and his son had actually forced the duke out of his coach in St James's street, and carried him away beyond Devonshire house, Piccadilly, before he was rescued from them. See BLOON.

It does not appear, however, that this transaction hurt the duke's interest at court; for in 1671 he was installed chancellor of the university of Cambridge, and sent ambassador to France. Here he was very nobly entertained by Lewis XIV. and presented by that monarch at his departure with a sword and belt set with jewels, to the value of 40,000 pistoles; and the next year he was employed in the second embassy to that king at Utrecht. However, in June 1674, he resigned the chancellorship of Cambridge, and about the same time became a zealous partizan and favourite of the Nonconformists. On the 16th of February 1676, his grace, with the earls of Salisbury and Shaftesbury and Lord Warton, were committed to the tower by order of the house of lords, for a contempt in refusing to retract the purport of a speech which the duke had made concerning a dissolution of the parliament. This confinement did not last long,

Villose,
Vinca.

yet we find no material transaction of this nobleman's life recorded after it, till the time of his death, which happened in 1687. Wood tells us that died at his house in Yorkhire; but Mr Pope, who must certainly have had very good information, and it is to be imagined would not have dared to advance an injurious falsehood of a person of his rank, has, in his epistle to Lord Bathurst, given us a most affecting account of the death of this ill-fated nobleman, whom, after having been master of near £ 50,000 *per annum*, he describes as reduced to the deepest distress by his vice and extravagance, and breathing his last moments in a mean apartment at an inn.

As to his personal character, it is impossible to say any thing in its vindication; for though his severest enemies acknowledge him to have possessed great vivacity and a quickness of parts peculiarly adapted to the purposes of ridicule, yet his warmest advocates have never attributed to him a single virtue. His generosity was profuseness, his wit malevolence, the gratification of his passions his sole aim through life, his very talents caprice, and even his gallantry the mere love of pleasure. But it is impossible to draw his character with equal beauty, or with more justice than in that given of him by Dryden, in his *Abraham and Achitophel*, under the name of *Zimri*, to which the reader is referred.

As a writer, however, he stands in a quite different point of view. There we see the wit, and forget the libertine.—His poems, which indeed are not very numerous, are capital in their kind; but what will immortalize his memory while language shall be understood, or true wit relished, is his celebrated comedy of *The Rehearsal*.

VILLOSE, or VILLOUS, something abounding with villi or fibres like short hair; such is one of the coats of the stomach.

VINCA, PERIWINKLE; a genus of the monogynia order, belonging to the pentandria class of plants. There are four species, three of which are commonly cultivated in our gardens, viz. 1. The minor, or smaller periwinkle, hath slender, ligenous, trailing, green stalks, branching and running considerably along the ground, emitting roots at the joints; garnished with oval, spear-shaped, thick, smooth, shining-green leaves, in pairs opposite; and flowers growing singly on proper peduncles at the sides of the branches, of different colours in the varieties.

2. The major, or large green periwinkle, rises with shrubby, somewhat erect, green stalks, a foot or two high, with tops inclining to the ground; large, oval, shining-green leaves, in pairs opposite; and large blue flowers singly on foot-stalks at the axillae of the branches. There is a variety with white flowers.—Both the species are perennial in root, stem, and branches, with leaves in perpetual verdure, and begin flowering in the spring, about March and April; the flowers moderately large, each being of one salver-shaped petal, spreading at the brim, and cut into five parts; generally continue flowering in succession several months, and even sometimes in winter, in mild seasons, especially the vinca major.

3. The rosea, or rose periwinkle of Madagascar, rises with an upright, shrubby, smooth, branching stem, a yard or more high; having a brownish bark; ob-

long-oval, smooth, firm leaves, placed opposite; and large beautiful, rose-like, crimson, and pale-red flowers, singly and in pairs at the sides of the branches, being large, spreading above, and divided into five segments; appearing very ornamentally from the spring till winter, succeeded by ripe seeds in the autumn.

The two former kinds may be propagated by layers, cuttings, and suckers; and will thrive any where; but the last being tender, must be constantly kept in a stove.

St VINCENT, one of the Caribbee islands, which received its name from being discovered on the 22d of January, the feast of that Saint. It lies from 13° to 13° 20' of north latitude, and in longitude 59° 40' west from London. At the distance of between 5 and 6 leagues south-west from St Lucia, 23 south-west from Martinico, 36, or, as some compute, 40 south of Dominica, 20 west-by-south from Barbadoes, and 17 or 18 north-east from Grenada. Being thus situated directly to the leeward of Barbadoes, it may in a few hours be reached from thence; and is at the same time so seated as to cover and connect the small islands that lie between it and Grenada. It stretches in length from south to north about 25 miles, and is about 13 in breadth; in circumference between 60 and 70. In point of size therefore it differs but little from Barbadoes. The climate is very warm; at least in the judgment of Europeans. The country is in general hilly, in some places mountainous; but interspersed with a variety of pleasant valleys, and some luxuriant plains, the soil being every where very fertile, and the high grounds are at least in general easy of ascent. Few islands of its extent are so well watered: for several rivers run down from the mountains, and smaller streams from almost every hill; there are likewise several fine springs at a little distance from the sea. The inhabitants raise all kinds of ground provisions in plenty, and with little trouble. The rivers supply them with a variety of fish; and the fame may be said of the sea that washes their coasts. They have abundance of excellent fruits, and very fine timber fit for almost every use; and with which they formerly supplied their neighbours.

The French, though they did not venture to raise sugars, had several spacious plantations at the mouths and on the sides of the rivers, planted with cacao trees, coffee, indigo, and fine tobacco. There are several commodious bays on the north-west and south-west sides; and at the southern extremity there is the deep spacious sandy bay, formerly styled the *Bay of St Antonio*, but now *Kingston Bay*, where large ships may ride commodiously: and there is said to be good anchoring ground round the whole island. It remained, for a long space of time after it was discovered by the Europeans, the head-quarters and general rendezvous of the Caribs and Caribs, who from thence made expeditions to the continent, and were also sometimes very troublesome to the adjacent islands. Besides these there are another race of people generally, though very improperly, styled *Black Caribs*, but who are in reality negroes descended, as is generally believed, from some who escaped out of a Guinea ship wrecked upon the coast, and gradually augmented by such as from time to time fled thither from Barbadoes. These nations were often at war; but when their quarrels were composed,

posed, they had a strength sufficient to prevent strangers from settling by force.

The French, about half a century ago, at the request of the Caribs, made a descent from Martinico, and attacked the negroes, but were repulsed with loss; and found it their interest to conciliate a friendship with both nations by means of presents, and furnishing them with arms and ammunition, which procured them the means of making those plantations that have been before-mentioned. At the treaty of Paris this island was given up to Britain, but has since been taken by the French. In 1770 its exports were, cotton, 284 bags, at 10*l.* *per* bag; 284*ol.* Coffee, 4818 hundred weight one quarter, six pound, at 3*l.* 5*s.* *per* hundred weight, 15,659*l.* 9*s.* 8*d.* Cacao, 1000 hogheads and one barrel, at 25*l.* *per* hoghead, and 12*l.* *per* barrel, 25,012*l.* Rum, 346 hogheads, at 10*l.* *per* hoghead, 3460*l.* Sugar, 2866 hogheads, at 17*l.* 10*s.* *per* hoghead, 50,155*l.* In all to Great Britain, 97,126*l.* 9*s.* 8*d.* To North America, 13,375*l.* Total 110,501*l.* 9*s.* 8*d.*

VINCENT (Nathaniel), an eminent dissenting minister, received his education at Christ Church in Oxford. He became a member of that university at 11 years of age, and when he was about 18 he took the degree of master of arts. He soon became a very famous preacher and writer; but refusing to comply with the act of uniformity, was not only one of the most assiduous, but one of the most unfortunate, of his non-conforming brethren. He was several times imprisoned, and heavily fined; for holding conventicles; and was once sentenced to suffer three years imprisonment, and then banishment, in pursuance of an act made in the 25th of Elizabeth; but his counsel finding a flaw in the indictment, the sentence was never carried into execution. He distinguished himself by preaching amidst the ruins after the fire of London, where multitudes assembled to hear him, many of whose consciences were awakened by that dreadful calamity. He was the author of many sermons, and other practical pieces of divinity; and died in 1679.

Thomas Vincent, his brother, a man of a similar character, exerted himself on the same occasion, as he did also in the time of the pestilence, when he constantly preached in London, and visited the sick, but escaped the distemper himself. He was the author of "God's terrible Voice to the City by Fire and Plague, 8vo;" and published another of the like kind, occasioned by an eruption of Mount *Ætna*, intitled *Fire and Brimstone*, 1. From heaven, in the burning of Sodom and Gomorrah formerly; 2. From earth, in the burning of Mount *Ætna* lately; 3. From hell, in the burning of the wicked eternally. He wrote several other works.

VINCI (Leonardo da), an illustrious Italian painter, descended from a noble Tuscan family, was born in the castle of Vinci near Florence in 1445. He was placed under Andrea Verocchio, a celebrated painter in that city; but soon surpassed him and all his predecessors so much, as to be reputed the master of the third or golden age of modern painting. But his studies were far from terminating here; no man's genius was more universal: he applied himself to arts, to literature, and to the accomplishments of the body; and he excelled in every thing he attempted. Lewis Sforza duke of Milan, prevailed on him to be director of the academy for architecture he had just established; where

Leonardo soon banished all the Gothic fashions, and reduced every thing to the happy simplicity of the Greek and Roman style. By the duke's order he constructed the famous aqueduct that supplies the city of Milan with water: this canal goes by the name of *Mortefiana*, being above 200 miles in length; and conducts the water of the river Adda quite to the walls of the city. In 1479, he was desired to construct some new device for the entertainment of Lewis XII. of France, who was then to make his entrance into Milan. Leonardo accordingly made a very curious automaton in the form of a lion, which marched out to meet the king, reared up on its hinder legs before him, and opening its breast, displayed an escutcheon with fleur de lys quartered on it. The disorders of Lombardy, with the misfortunes of his patrons the Sforzi, obliging Leonardo to quit Milan, he retired to Florence, where he flourished under the Medici: here he railed the envy of Michael Angelo, who was his cotemporary; and Raphael, from the study of his works, acquired his best manner of designing. At length, on the invitation of Frances I. he removed to France when above 70 years of age; where the journey and change of climate threw him into his last sickness: he languished for some months at Fontainebleau, where the king came frequently to see him; and one day rising up in his bed to acknowledge the honour done him, he fainted, and Francis supporting him, Leonardo died in his arms. His death happened in 1520. Some of his paintings are to be seen in England and other countries, but the greatest part of them are in Florence and France. He composed a great number of discourses on curious subjects; but none of them have been published but his treatise on the Art of Painting.

VINE, in botany. See VITIS.

VINEGAR, ACETUM, an agreeable acid and penetrating liquor, prepared from wine, cyder, beer, and others liquors; of considerable use, both as a medicine and a sauce. The word is French, *vinagre*; formed from *vin*, "wine;" and *aigre*, "sour." See ACETUM and WINE.

Wine and other vinous liquors are said to gain a grateful sharpness, *i. e.* to become vinegar, by having their salts extraded by insolation or other means, and their sulphurs weakened or depressed.

Others ascribe the conversion of vinous liquors into vinegar, to the grinding or sharpening of the longitudinal particles thereof; by which means they become more sharp and pungent.

The method of making vinegar has long been kept a secret among the people of that profession; who, it is said, oblige themselves to each other by an oath not to reveal it: but notwithstanding this, the Philosophical Transactions, and some other late writings, furnish us with approved accounts thereof.

Method of making Cyder VINEGAR.—The cyder (the meanest of which will serve the purpose) is first to be drawn off fine into another vessel, and a quantity of the must of apples to be added: the whole is set in the sun, if there be convenience for it; and at a week or nine days end it may be drawn off. See CYDER.

Method of making Beer VINEGAR.—Take a middling sort of beer, indifferently well hopped; into which, when it has worked well and grown fine, put some rape,

Vinegar.

rape, or husks of grapes, usually brought home for that purpose: mash them together in a tub; then letting the rape settle, draw off the liquid part, put it into a cask, and set it in the sun as hot as may be; the bung being only covered with a tile, or slate-stone: and in about 30 or 40 days it will become a good vinegar, and may pass in use as well as that made of wine, if it be refined, and kept from turning musty.

Or thus:—To every gallon of spring-water add three pounds of Malaga raisins; which put into an earthen jar, and place them where they may have the hottest sun from May till Michaelmas; then pressing all well, tun the liquor up in a very strong iron-hooped vessel, to prevent its burbling: it will appear very thick and muddy when newly pressed; but will refine in the vessel, and be as clear as wine.—Thus let it remain untouched for three months before it is drawn off, and it will prove excellent vinegar.

To make Wine VINEGAR.—Any sort of vinous liquor being mixed with its own feces, flowers, or ferment, and its tartar first reduced to powder; or else with the acid and anther stalks of the vegetable from whence the wine was obtained, which hold a large proportion of tartar; and the whole being kept frequently stirring in a vessel which has formerly held vinegar, or set in a warm place full of the fumes of the same, will begin to ferment anew, conceive heat, grow four by degrees, and soon after turn into vinegar.

The remote subjects of acetous fermentation are the same with those of vinous; but the immediate subjects of it, are all kinds of vegetable juices, after they have once undergone that fermentation which reduces them to wine: for it is absolutely impossible to make vinegar of must, the crude juice of grapes, and other ripe fruits, without the previous assistance of vinous fermentation.

The proper ferments for this operation, whereby vinegar is prepared, are, 1. The feces of all acid wines. 2. The lees of vinegar. 3. Pulverized tartar, especially that of Rhenish wine, or the cream or crystals thereof. 4. Vinegar itself. 5. A wooden vessel well drenched with vinegar, or one that has long been employed to contain it. 6. Wine that has often been mixed with its own feces. 7. The twigs of vines, and the stalks of grapes, currants, cherries, or other vegetables of an acid anther taste. 8. Bakers leaven, after it is turned acid. 9. All manner of ferments, compounded of those already mentioned.

Vinegar is no production of nature, but a creature of art: for verjuice, the juices of citrons, lemons, and the like native acids, are improperly said to be *natural vinegars*; because, when distilled, they afford nothing but rapid water: whereas it is not the property of vinegar to yield an acid spirit by distillation.

Method of making VINEGAR in France.—The French use a method of making vinegar different from that above described.—They take two very large oaken vessels, the larger the better, open at the top; in each whereof they place a wooden grate, within a foot of the bottom; upon these grates they first lay twigs or cuttings of vines, and afterwards the stalks of the branches, without the grapes themselves, or their stones, till the whole pile reaches within a foot of the brim of the vessels; then they fill one of these vessels with wine to the very top, and half fill the other; and with li-

Vol. X.

quor drawn out of the full vessel, fill up that which was only half full before; daily repeating the same operation, and pouring the liquor back from one vessel to the other; so that each of them is full and half-full by turns.

When this process has been continued for two or three days, a degree of heat will arise in the vessel which is then but half full, and increase for several days successively, without any appearance of the like in the vessel which happens to be full during those days, the liquor whereof will still remain cool: and as soon as the heat ceases in the vessel that is half full, the vinegar is prepared: which, in the summer, happens on the 14th or 15th day from the beginning; but in the winter, the fermentation proceeds much slower, so that they are obliged to forward it by artificial warmth or the use of stoves.

When the weather is exceeding hot, the liquor ought to be poured off from the full vessel into the other twice a-day; otherwise the liquor would be over-heated, and the fermentation prove too strong: whence the spirituous parts would fly away, and leave a rapid wine instead of vinegar behind.

The full vessel is always to be left open at the top; but the mouth of the other must be cloisted with a cover of wood, in order the better to keep down and fix the spirit in the body of the liquor; for otherwise it might easily fly off in the heat of fermentation. The vessel that is only half full seems to grow hot rather than the other, because it contains a much greater quantity of the vine-twigs and stalks, than that in proportion to the liquor; above which the pile rising to a considerable height, conceives heat the more, and so conveys it to the wine below.

VINEGAR Concentrated. See CHEMISTRY, n° 287.

VINEGAR, (Salt of.) See CHEMISTRY, n° 288.

Eels in VINEGAR. See ANIMALCULE, n° 8.

VINEYARD, a plantation of vines. The best situation of a vineyard is on the declivity of a hill facing the south.

VIO (Thomas de). See CAJETAN.

VIOL, a musical instrument of the same form with the violin, and, like that, struck with a bow.

VIOLA, the VIOLET; a genus of the monogynia order, belonging to the lyngensia class of plants. There are many species. The odorata, odoriferous, or common sweet-scented March violet, with the flowers of different colours in the varieties, appearing in March. The flowers impart a fine sweet odour, and are used in medicine. It grows naturally in woods, and under hedges, &c. in most parts of Europe; but has been a long resident of gardens as a flowery plant, and for its use in medicine.

2. The tricolor, or three-coloured violet, commonly called *heart's-ease*, or *passey*, assumes a bushy, tufted growth; and at the axillas of the branches are numerous variegated, three-coloured flowers, yellow, purple, and white, appearing in constant succession all summer and autumn. It grows naturally in cultivated places in the north of England, &c.

This elegant little plant merits culture in every garden, for the beauty and great variety of its three-coloured flowers; and it will succeed anywhere where in the open borders, or other compartments, disposed in patches towards the front; either by sowing the seed at once to remain,

Virgil.

remain, or by putting in young plants previously raised in a feed-bed: they will begin flowering early in summer, and will continue shooting and flowering in succession till winter; and even during part of that season in cold weather.

The common violet is propagated by parting the roots, sometimes by seed.

VIOLATION, the act of violating, that is, forcing a woman, or committing a rape upon her.—This term is also used in a moral sense, for a breach or infringement of a law, ordinance, or the like.

VIOLET, in botany. See **VIOLA**.

VIOLET-Grab, in zoology. See **CANCER**.

VIOLIN, or **FIDDLE**, a musical instrument mounted with four strings or guts, and struck or played with a bow. The style and sound of the violin is the gayest and most sprightly of all other instruments; and hence it is of all others the fittest for dancing. Yet there are ways of touching it, which render it grave, soft, languishing, and fit for church or chamber music.—It generally makes the treble, or highest parts in concerts. Its harmony is from fifth to fifth. Its play is composed of bass, counter-tenor, tenor, and treble; to which may be added, a fifth part: each part has four fifths, which rise to a greater seventeenth.

VIOLONCELLO, of the Italians, is properly our fifth violin; which is a little bass violin half the size of the common bass violin, and the strings bigger and longer in proportion: consequently its sound is an octave lower than our bass violin; which has a noble effect in concerts.

VIPER, in zoology. See **COLUMBER**.

VIRAGO, a woman of extraordinary stature and courage; and who, with the female sex, has the mien and air of a man, and performs the actions and exercises of men.

VIRGIL, or **PUBLIUS VIRGILIUS MARO**, the most excellent of all the Latin poets, was the son of a potter of Andes, near Mantua, where he was born, 70 years B. C. He studied first at Mantua; then at Cremona, Milan, and Naples; whence going to Rome, he acquired the esteem of the greatest wit and most illustrious persons of his time; and among others, of the emperor Augustus, Mæcenas, and Pollio. He was well skilled not only in polite literature and poetry, but also in philosophy, the mathematics, geography, medicine, and natural history. Though one of the greatest geniuses of his age, and the admiration of the Romans, he always preserved a singular modesty, and lived chaste at a time when the manners of the people were extremely corrupt. He carried Latin poetry to such an high perfection, that he was justly esteemed the prince of Latin poets. He first turned himself to pastoral; and being captivated with the beauty and sweetness of Theocritus, was ambitious to introduce this new species of poetry among the Romans. His first performance in this way is supposed to have been written U. C. 709, the year before the death of Julius Cæsar, when the poet was in his 25th year: it is intitled *Alexis*. Possibly *Palemon* was his second: it is a close imitation of the fourth and fifth Idylls of Theocritus. Mr Warton places *Silenus* next; which is said to have been publicly recited on the stage by Cytheris, a celebrated comedian. Virgil's fifth eclogue is composed in allusion to the death and deifi-

cation of Cæsar. The battle of Philippi in 712 having put an end to the Roman liberty, the veteran soldiers began to murmur for their pay; and Augustus, to reward them, distributed among them the lands of Mantua and Cremona. Virgil was involved in this common calamity; and applied to Varus and Pollio, who warmly recommended him to Augustus, and procured for him his patrimony again. Full of gratitude to Augustus, he composed the *Tityrus*, in which he introduces two shepherds: one of them complaining of the distraction of the times, and of the havoc the soldiers made among the Mantuan farmers; the other rejoicing for the recovery of his estate, and promising to honour as a God the person who restored it to him. But our poet's joy was not of long continuance; for we are told, that when he returned to take possession of his farm, he was violently assaulted by the intruder, and would certainly have been killed by him if he had not escaped by swimming hastily over the Mincio. Upon this unexpected disappointment, he returned to Rome to renew his petition; and during his journey seems to have composed his ninth eclogue. The celebrated eclogue, intitled *Pollio*, was composed U. C. 714, upon the following occasion. The consul Pollio on the part of Antony, and Mæcenas on the part of Cæsar, had made up the differences between them; by agreeing, that Octavia, half-sister to Cæsar, should be given in marriage to Antony. This agreement caused an universal joy; and Virgil, in his eclogue, testified his. Octavia was with child by her late husband Marcellus at the time of this marriage; and whereas the Sybilline oracles had foretold, that a child was to be born about this time, who should rule the world, and establish perpetual peace, the poet ingeniously supposes the child in Octavia's womb to be the glorious infant, under whose reign mankind was to be happy, the golden age to return from heaven, and fraud and violence to be no more. In this celebrated poem, the author with great delicacy at the same time pays his court to both the chiefs, to his patron Pollio, to Octavia, and to the unborn infant. In 715, Pollio was sent against the Parthini, a people of Illyricum; and during this expedition, Virgil addressed to him a beautiful eclogue, called *Pharmacutria*. His tenth and last eclogue was addressed to Gallus. These were our poet's first productions; and we have been the more circumstantial in our account of some of them, as many particulars of his life are intimately connected with them.

Being in his 34th year, he retired to Naples, and laid the plan of his inimitable *Georgics*; which he undertook at the intreaties of Mæcenas, to whom he dedicated them: not to rival and excel Hesiod, as he had lately done Theocritus, but on a noble political motive, and to promote the welfare of his country. Great was the desolation occasioned by the civil wars: Italy was almost depopulated; the lands were uncultivated and unstocked; a famine and insurrection ensued; and Augustus himself hardly escaped being stoned by the people, who attributed this calamity to his ambition. His wife and able minister therefore resolved, if possible, to revive the decayed spirit of husbandry; to introduce a taste for agriculture, even among the great; and could not think of a better method to effect this, than to recommend it by the insinuating charms of poetry. Virgil fully answered the expectations of his polite patron, by

Virgil.

by his Georgics. They are divided into four books. Corn and ploughing are the subject of the first, vines of the second, cattle of the third, and bees of the fourth.

He is supposed to have been in his 45th year when he began to write the *Æneid*; the design of which is thus explained by Mr Spence in his *Polymetis*. Augustus being freed from his rival Antony, the government of the Roman empire was to be wholly in him; and though he chose to be called their father, he was, in every thing but the name, their king. But the monarchical form of government must naturally displease the Romans; and therefore Virgil, like a good courtier, seems to have laid the plan of his poem to reconcile them to it. He takes advantage of their religious turn, and of some old prophecies that must have been very flattering to the Roman people, as promising them the empire of the whole world. He weaves this in with the most probable account of their origin; that of their being descended from the Trojans. He shows, that *Æneas* was called into their country by the express order of the gods; that there was an uninterrupted succession of kings from him to Romulus; that Julius Cæsar was of the royal race, and that Augustus was his sole heir. The result of all this was, that the promises made to the Roman people in and through this race, terminating in Augustus, the Romans, if they would obey the gods, and be masters of the world, were to yield obedience to the new establishment under that prince. Augustus was eager to peruse this poem before it was finished; and intreated him by letters to communicate it. Macrobius has preferred to us part of one of Virgil's answers to the emperor, in which the poet excuses himself: who, however, at length complied, and read himself the sixth book to the emperor; when Octavia, who had just lost her son Marcellus, the darling of Rome, and adopted son of Augustus, made one of the audience. Virgil had artfully inserted that beautiful lamentation for the death of young Marcellus, beginning with—*O nate, ingentem luctum ne quæreaturum*—but suppressed his name, till he came to the line—*Tu Marcellus eris*: upon hearing which, Octavia could bear no more, but fainted away; overcome with surprise and sorrow. When she recovered, she made the poet a present of ten selterces for every line, which amounted in the whole to above 2000l.

The *Æneid* being brought to a conclusion, but not to the perfection our author intended to give it, he resolved to travel into Greece to correct and polish it at leisure. It was probably on this occasion that Horace addressed that affectionate ode to him, *Sic te Divæ potentis Cyprî, &c.* Augustus returning victorious from the east, met with Virgil at Athens, who thought himself obliged to attend the emperor to Italy: but the poet was suddenly seized with a fatal distemper, which being increased by the agitation of the vessel, put an end to his life as soon as he landed at Brundisium, in his 52d year. He had ordered in his will, that the *Æneid* should be burnt as an unfinished poem; but Augustus forbid it, and had it delivered to Varius and Tucca, with the strict charge to make no additions, but only to publish it correctly. He died with such steadiness and tranquillity, as to be able to dictate his own epitaph in the following words:

*Mantua me genuit: Calabri rapuere, tenet nunc
Parthenope: cecini Pæsiua, Rura, Duces.*

His bones were carried to Naples, according to his earnest request; and a monument was erected at a small distance from the city.

Virgil was of a swarthy complexion, tall, of a sickly constitution, and afflicted with frequent head-achs and spitting of blood. He was so very bashful, that he often ran into the shops to prevent being gazed at in the streets; yet was so honoured by the Roman people, that once coming into the theatre, the whole audience rose up out of respect to him. He was of a thoughtful and melancholy temper; he spoke little, and loved retirement and contemplation. His fortune was affluent; he had a fine house and well-furnished library near Mæcenas's gardens, on the Esquiline mount at Rome, and also a delightful villa in Sicily. He was so benevolent and inoffensive, that most of his contemporaries poets, though they envied each other, agreed in loving and esteeming him. He revised his verses with prodigious severity; and used to compare himself to a she-bear, which licked her cubs into shape.

The best edition of Virgil's works are those of Mosvicius, with the notes of Servius, printed at Lewarden in 1717, 2 vols. 4to; and that of Burman, at Amsterdam, 1746, in 4 vols. 4to. There are several English translations, which are well known.

VIRGIL (Polydore), an English historian, born at Urbino in Italy, was sent in the beginning of the 16th century, by pope Alexander VI. as sub-collector of the Papal tax, called *Peter-pence*, in this kingdom. He had not been long in England before he obtained preferment in the church; for in 1503 he was presented to the rectory of Church-Langton in the archdeaconry of Leicester. In 1507, he was collated to the prebend of Scamlesby in the church of Lincoln; and in the same year was made archdeacon of Wells, and prebendary of Hereford. In 1513, he resigned his prebend of Lincoln, and was collated to that of Osgate, in St Paul's, London. We are told, that on his preferment to the archdeaconry of Wells, he resigned the office of sub-collector to the pope, and determined to spend the remainder of his life in England, the History of which kingdom he began in the year 1505, at the command of Henry VII. That work cost him 12 years labour. In 1526, he finished his treatise on Prodigies. Polydore continued in England during the whole reign of Henry VIII. and part of that of Edward VI. whence it is concluded that he was a moderate Papist. In 1550, being now an old man, he requested leave to revisit his native country. He was accordingly dismissed with a present of 300 crowns, together with the privilege of holding his preferments to the end of his life. He died at Urbino in the year 1555. As an historian, he is accused by some as a malignant slanderer of the English nation; yet Jovius remarks, that the French and Scotch accuse him of having flattered that nation too much: see his *Elog.* cap. 135. p. 179. Besides the above, he wrote, 1. *De rerum inventoriis*; of which an English translation was published by Langley in 1663. It was also translated into French and Spanish. 2. *De prodigiis et fortibus*. 3. *Episcoporum Angliæ catalogus*. Manuscript. 4. *De vita perfecta*. Bais, 1546, 1553, 8vo. 5. *Epistolæ crudite*; and some other works.

VIRGIN, a female who has had no carnal commerce with man.

Virgil,
Vigin.

VIRGIN is also figuratively applied to several things that retain their absolute purity, and have never been made use of.

VIRGINIA, late one of the British colonies, now one of the United States of North America; bounded on the south by Carolina, on the north-east by the river Patowmack which divides it from Maryland, on the east by the Atlantic Ocean, and on the west by the Apalachian mountains; extending about 240 miles in length, and 200 in breadth.

The air and seasons here depend very much upon the wind, as to heat and cold, dryness and moisture. The north and north-west winds are piercing cold, and clear, or else stormy; the south-east and south, lazy and sultry hot. In winter they have a fine clear air, and dry, which renders it very pleasant. Their frosts are short; but sometimes so very sharp, that rivers three miles broad will be frozen over. Snow falls sometimes in pretty large quantities, but rarely lies above a day or two. Their spring is about a month earlier than in England; in April they have frequent rains; in May and June the heat increases; and the summer is much like our's, being mitigated with gentle breezes that rise about nine o'clock, and decrease and increase as the sun rises or falls. In July and August these breezes cease, and the air becomes sultry and hot: in September the weather generally changes suddenly, and heavy rains fall, and then the inhabitants are generally very sickly. It is to be observed, however, that here, and in all the other states, as the cultivation and population of them advances, the air grows better, to which the cutting down of the woods greatly contributes.

As to the face of the country in Virginia, it is generally low and flat towards the sea-coast, and for 100 miles up the country; so that there is hardly a hill or stone to be seen, except here and there some rocks of iron ore, and some banks of a kind of petrified oyster-shells. The whole country, before it was planted, was one continued forest, interspersed with marshes, which in the West Indies they call *savamps*. No country now produces greater quantities of excellent tobacco; and the soil is generally so sandy and shallow, that after they have cleared a fresh piece of ground out of the woods, it will not bear tobacco after two or three years, unless covered-penned and well dunged.

The forests here yield oaks, poplars, pines, cedars, cypresses, sweet myrtles, chestnuts, hickory, live oak, walnut, dog-wood, alder, hazel, chinkapins, locust-trees, saltstems, elm, ash, beech, with a great variety of sweet gums and incense, which distil from several trees; pitch, tar, rosin, turpentine, plank-timber, masts, and yards. Virginia yields also rice, hemp, Indian corn, plenty of pasture, with coal, quarries of stone, and lead and iron ore.

Of spontaneous flowers there are a great variety here, particularly the flaxen crown-imperial in the world, and the cardinal-flower so much extolled for its scarlet colour; almost the whole year round the plains and valleys are adorned with flowers of one kind or another. In this country also is found the tulip bearing laurel-tree, which has the pleasantest smell in the world, and keeps seeds and blossoms several months together.

Silk-grass grows spontaneous in many places; the fibres of which are as fine as flax, and much stronger than hemp. Their trees are much softer than our's,

and no underwood or bushes grow beneath; so that people travel with ease through the forests on horse-back, and never want a fine shade to defend them from the summer heats.

Among other animals in Virginia are elks, but not common; red deer in great plenty; musk rats, racoons, beavers, and wolves. As for reptiles, they have lizards, with several kinds of snakes, particularly the rattle-snake. Of birds, they have several sorts of eagles, hawks, and owls, mocking-birds, and humming-birds.

Besides the animals that are natives of the country, most of the quadrupeds of Europe have been introduced here; such as horses, cows, sheep, and hogs, which are prodigiously multiplied, great numbers running wild in their forests, besides what they have tame in their plantations. In February, March, April, and May, shoals of herrings come up into their very brooks; some of the size of ours, but for the most part much larger. They have great quantities in summer of those destructive worms that eat into the bottoms of ships, wherever they find the coat of pitch, tar, or lime, worn off the timber; these worms have a kind of horn or scrow in their head, with which they force a passage through any wood to which they stick.

Four great rivers, namely James River, York River, Rappahannock, and Patowmack, which rise in the Apalachian mountains, run through this province, or along its borders, from the north-west to the south-east, and fall into the bay of Chesapeake. James River is generally about two miles over, and navigable at least 80. York and Rappahannock are not so large; but Potowmack is navigable for near 200 miles, being generally seven miles broad, and in some places nine. The great bay of Chesapeake runs up through Virginia and Maryland, almost due north, 300 miles and upwards, being navigable most part of the way for large ships. The two promontories that form the mouth of the bay, are called *Cape Charles* and *Cape Henry*.

VIRGINITY, the test or criterion of a virgin; or that which entitles her to the denomination. See *HYMEN*.

VIRGO, in astronomy, one of the signs or constellations of the zodiac. See *ASTRONOMY*, n° 110.

VIRILE, something that belongs, or is peculiar, to a man, or the male sex.

VIRTUAL, or POTENTIAL; something that has a power or virtue of acting or doing. The term is chiefly understood of something that acts by a secret invisible cause, in opposition to actual and sensible.

VIRTUE, a term used in various significations. In the general it denotes power, or perfection of any thing, whether natural or supernatural, animate or inanimate, essential or accessory. But, in its more proper or restrained sense, virtue signifies a habit, which improves and perfects the possessor and his actions. See *MORALS*, n° 27, 28, 72, 73, &c. and *METAPHYSICS*, n° 119—137.

VIRTUOSO, an Italian term lately introduced into the English, signifying a man of curiosity and learning, or one who loves and promotes the arts and sciences. But among us the term seems to be appropriated to those who apply themselves to some curious and quaint, rather than immediately useful art, or study; as antiquaries, collectors of rarities of any kind, microscopical observers, &c.

VIRULENT
Virus.

VIRULENT, a term applied to any thing that yields a virus; that is, a contagious or malignant pus.

VISCERA, in anatomy, a term signifying the same with entrails; including the heart, liver, lungs, spleen, intestines, and other inward parts of the body.

VISCIDITY, or **VISCOSITY**, the quality of something that is viscid or viscous; that is glutinous, and sticky like bird-lime, which the Latins call by the name of *viscus*.

VISCOUNT (*Vice Comes*), was anciently an officer under an earl, to whom, during his attendance at court, he acted as deputy to look after the affairs of the country. But the name was afterwards made use of as an arbitrary title of honour, without any shadow of office pertaining to it, by Henry VI.; when, in the 18th year of his reign, he created John Beaumont a peer, by the name of *viscount Beaumont*; which was the first instance of the kind.

A viscount is created by patent as an earl is; his title is *Right Honourable*; his mantle is two doublings and a half, of plain fur; and his coronet has only a row of pearls close to the circle.

VISIBLE, something that is an object of sight or vision; or something whereby the eye is affected so as to produce this sensation.

VISSIER, an officer or dignitary in the Ottoman empire, whereof there are two kinds; one called by the Turks *Vissier-azem*, that is, "grand visier," is the prime minister of state in the whole empire. He commands the army in chief, and presides in the divan or great council. Next to him are six other subordinate visiers, called *visiers of the bench*; who officiate as his counsellors or assessors in the divan.

VISION, in optics, the art of seeing or perceiving external objects by means of the organ of sight, the eye. See **ANATOMY**, l^o 466, and *Index* subjoined to **OPTICS**.

VISTULA, or **WEISSEL**, a large river of Poland, which taking its rise in the mountains south of Silesia, visits Cracow, Warsaw, &c. and continuing its course northward, falls into the Baltic sea below Danzig.

VISUAL, in general, something belonging to vision.

VITAL, in physiology, an appellation given to whatever ministers principally to the constituting or maintaining life in the bodies of animals: thus the heart, lungs, and brain, are called *vital parts*; and the operations of these parts by which the life of animals is maintained are called *vital functions*.

VITELLUS, the yolk of an egg. See **EGG** and **YOLK**.

VITIS, the **VINE**; a genus of the angiosperma order, belonging to the didynamia class of plants. There are seven species, and a great many varieties, the enumeration of all which would be too tedious to insert here. Mr Millar enumerates the following, which are easily propagated and ripen well in this country. 1. The July grape, called by the French *Morillon noir batif*, is a small, round, black berry, growing loose on the bunches. The juice is sugary; but has little flavour, and has no merit but that of ripening early. It ripens the beginning of August. 2. The black sweet-water, is a small roundish berry, growing close in the bunches, which are short. The skin is thin, the juice very sweet, and the birds and flies are very apt to devour them if they are not

guarded. It ripens soon after the other. 3. The white sweet-water, is a large round berry when in perfection; but these are very different in size on the same bunch; some of them will be of a large size, and others extremely small, for which reason it is not much esteemed. The juice is sugary, but not vinous. This ripens about the same time with the former. 4. The Chasselas blanc, or royal Muscadine, as it is called by some, is an excellent grape; the bunches are generally large, and at the upper part divided with two smaller side bunches or shoulders. The berries are round; and, when perfectly ripe, turn of an amber colour. The juice is rich and vinous: it ripens in September; but, if carefully preserved, they will hang very late, and become excellent. 5. The Chasselas musque, or *le cour grape*, as it is here called, by some called the *Frankindal*, is an excellent grape, and generally ripens well in England, if it has a good aspected wall. The berries are very like those of the former in shape, size, and colour; but are fleshy, and have a little musky flavour. It ripens at the same time with the former. 6. The black cluster, or *Manier* grape, as it is called by the French, from the hoary down of the leaves in summer, is a good fruit, and ripens well here. The bunches are short, the berries are oval, and are very close to each other; so that many of those which grow on the inside continue green when the outer are perfectly ripe. It ripens in September, and is by some called the *Burgundy* grape. 7. The auverna, or true Burgundy grape, sometimes called *black morillon*, is an indifferent fruit for the table; but is esteemed one of the best sorts for making wine. The berries of this are oval, and hang looser on the bunches than those of the cluster grape; so ripen equally, which gives it the preference. 8. The Corinth, or as it is vulgarly called the *currant grape*, is a small roundish berry, generally without stones, of a deep black colour, and much clustered on the bunches, which are short; it has a sugary juice, and ripens in September, but will not last long. 9. The red Chasselas, is very like the white in size and shape; but is of a dark red colour: it is a very good grape; but ripens later than the white, and is pretty rare in England. 10. The white muscadine, is something like the chasselas; but the berries are smaller, and hang looser on the bunches, which are longer, but not so thick as those of the chasselas. The juice is sweet, but not so rich as the chasselas. 11. The black frontinac, or muscat noir, is a round berry of good size; they grow loose on the bunches, yet do not ripen equally. The bunches are short; the berries, when fully ripe, are very black; and are covered with a meal or flue, like the black plums. The juice of this is very rich and vinous. It ripens in the end of September, or the beginning of October. 12. The red frontinac, or muscat rouge, is an excellent grape when fully ripe; but unless the season proves very warm, they rarely ripen without artificial heat in England. The bunches of this sort are longer than those of the former: the berries are large and round: when they are fully ripe, they are of a brick colour; but before, they are gray, with a few dark stripes: and this is frequently taken for a different kind, and is commonly called *grisley frontinac*; but I am convinced it is the same grape. The juice of

this

this has the most vinous flavour of all the sorts, and is greatly esteemed in France. 13. The white frontina; has larger bunches than either of the former: the berries are round, and are so closely clustered on the bunches, that unless they are carefully thinned early in the season, when the berries are very small, the sun and air will be excluded from many of them, so that they will not ripen, and the moisture will be detained in the autumn, which will cause them to rot. The juice of this is excellent; and, if the fruit is perfectly ripe, is inferior to none. The French call it *muscat blanc*. 14. The Alexandrian frontina, or muscat d'Alexandre, is by some called *muscat of Jerusalem*. The berries of this are oval, and hang loose on the bunches; these are long, and are not shouldered. There are two sorts, one with white and the other with red berries; their juice is very rich and vinous, but they seldom ripen in England without artificial heat. 15. The red and black Hamburg, by some called the *Warner grape*, from the person who brought it into England. These have middle-sized berries inclining to an oval shape. The bunches are large; and their juice, when ripe, is fugary, with a vinous flavour. This ripens in October. 16. The St Peter's grape has a large oval berry, of a deep black colour when ripe. The bunches are very large, and make a fine appearance at the table; but the juice is not rich, and it ripens late in the year. The leaves of this sort are much more divided than those of the other sorts, approaching to those of the parsley-leaved grape, so it may be distinguished before the fruit is ripe.

All the sorts of grapes are propagated either from layers or cuttings, the former of which is greatly practised in England, but the latter is much preferable.

In choosing the cuttings, you should always take such shoots as are strong and well ripened of the last year's growth; these should be cut from the old vine, just below the place where they were produced, taking a knot, or piece of the two-years wood to each, which should be pruned smooth; then you should cut off the upper part of the shoots, so as to leave the cutting about sixteen inches long. When the piece or knot of old wood is cut at both ends, near the young shoot, the cutting will resemble a little mallet; from whence Columella gives the title of *malleolus* to the vine-cuttings. In making the cuttings after this manner, there can be but one taken from each shoot; whereas most persons cut them into lengths of about a foot, and plant them all: which is very wrong, for various reasons too tedious to mention.

When the cuttings are thus prepared, if they are not then planted, they should be placed with their lower part in the ground in a dry soil, laying some litter upon their upper parts to prevent them from drying: in this situation they may remain till the beginning of April, (which is the best time for planting them); when you should take them out, and wash them from the filth they have contracted; and if you find them very dry, you should let them stand with their lower parts in the water six or eight hours, which will distend their vessels, and dispose them for taking root. Then the ground being before prepared where the plants are designed to remain (whether against walls or for standards, (for they should not be removed again), the cuttings should be planted. But

in preparing the ground, you should consider the nature of the soil; which if strong, and inclinable to wet, is by no means proper for grapes: therefore, where it so happens, you should open a trench where the cuttings are to be planted, which should be filled with lime rubbish, the better to drain off the moisture: then raise the borders with fresh light earth about two feet thick, so that it may be at least a foot above the level of the ground: then you should open the holes at about six feet distance from each other, putting one good strong cutting into each hole, which should be laid a little sloping, that their tops may incline to the wall; but it must be put in so deep, as that the uppermost eye may be level with the surface of the ground; for when any part of the cutting is left above ground, most of the buds attempt to shoot, so that the strength of the cuttings is divided to nourish so many shoots, which must consequently be weaker than if only one of them grew; whereas, on the contrary, by burying the whole cutting in the ground, the sap is all employed on one single shoot, which consequently will be much stronger; besides, the sun and air are apt to dry that part of the cutting which remains above ground, and so often prevents their buds from shooting.

Then having placed the cutting into the ground, you should fill up the hole gently, pressing down the earth with your foot close about it, and raise a little hill just upon the top of the cutting, to cover the upper eye quite over, which will prevent it from drying. This being done, there is nothing more necessary but to keep the ground clear from weeds until the cuttings begin to shoot; at which time you should look over them carefully, to rub off any small shoots, if such are produced, fastening the first main shoot to the wall, which should be constantly trained up, as it is extended in length, to prevent its breaking or hanging down. You must continue to look over these once in about three weeks during the summer season, constantly rubbing off all lateral shoots which are produced; and be sure to keep the ground constantly clear from weeds, which, if suffered to grow, will exhaust the goodness of the soil and starve the cuttings. The Michaelmas following, if your cuttings have produced strong shoots, you should prune them down to two eyes. In the spring, after the cold weather is past, you must gently dig up the borders to loose the earth; but you must be very careful, in doing this, not to injure the roots of your vines: you should also raise the earth up to the stems of the plants, so as to cover the old wood, but not so deep as to cover either of the eyes of the last year's wood. After this they will require no farther care until they begin to shoot; when you should look over them carefully, to rub off all weak dangling shoots, leaving no more than the two shoots, which are produced from the two eyes of the last year's wood, which should be fastened to the wall. And so from this, until the vine have done shooting, you should look them over once in three weeks or a month, to rub off all lateral shoots as they are produced, and to fasten the main shoots to the wall as they are extended in length; which must not be shortened before the middle or latter end of July, when it will be proper to nip off their tops, which will strengthen the lower eyes; and during the summer

mer season you must constantly keep the ground clear from weeds : nor should you permit any sort of plants to grow near the vines, which would not only rob them of nourishment, but shade the lower parts of the shoots, and thereby prevent their ripening; which will not only cause their wood to be spongy and luxuriant, but render it less fruitful.

As soon as the leaves begin to drop in autumn, you should prune these young vines again, leaving three buds to each of the shoots, provided they are strong : otherwise it is better to shorten them down to two eyes if they are good; for it is a very wrong practice to leave much wood upon young vines, or to leave their shoots too long, which greatly weakens the roots: then you should fasten them to the wall, spreading them out horizontal each way, that there may be room to train the new shoots the following summer, and in the spring the borders must be digged as before.

The uses of the fruit of the vine for making wine, &c. are well known. However, the number of vines cultivated in this country is by no means sufficient to supply the consumption. The plant was introduced by the Romans, and appears formerly to have been very common. From the name of vineyard yet adhering to the ruinous sites of our castles and monasteries, there seem to have been few in the country but what had a vineyard belonging to them. The county of Gloucester is particularly commended by Malmesbury in the twelfth century, as excelling all the rest of the kingdom in the number and goodness of its vineyards. In the earlier periods of our history, the Isle of Ely was expressly denominated the Isle of Vines by the Normans. Vineyards are frequently noticed in the descriptive accounts of doomsday. And those of England are even mentioned by Bede, as early as the commencement of the eighth century.

That the Romans were the original introducers of the plant, we need no other testimony than the British appellations of it. Being brought by them into Gaul, it was denominated the *vigne* by the natives. And, being carried by them into Britain, it was similarly called by the inhabitants the *guin-nyden*, the *guin-bren*, the *guin-ien*, or *fin-ras*, as it is still denominated in the Welsh, Cornish, Armorican, and Irish dialects. These appellations, like the Gaelic, do not directly signify the vine, and only speak of it characteristically as the wine-tree. And, as they show the Romans to have been the first planters of it in both kingdoms; so this little peculiarity pretty plainly intimates the natives of both to have been acquainted with the liquor, some time before they cultivated the tree. Such would naturally be the case of both. Such appears to have been actually the case with the Gauls. And the Caledonian Britons, who were strangers to the plant, were conversant with its produce before the middle of the third century.

The former was not brought into Britain in the first, but was introduced before the close of the third. And, confined as it would for ages be within the pale of the Roman government, it was transplanted into Ireland before the beginning of the eighth. But the grape, or, as with an agreeable simplicity it was called by the Britons, the *corne of the tree*, the *wine-grape*, and the *apple of the vine*, was not, as it now is, merely raised for the uses of the table. All the arts

of the vignerons would naturally be introduced with the plant. They were carried with it into Gaul. And, that they came together into Britain, the good knowledge which the Caledonians appear to have had of the liquor is a presumptive evidence, and the British appellation of the wine-tree for the vine seems a strong argument. But doomsday exhibits to us a particular proof made in England, during the period preceding the conquest. And, after it, the bishop of Ely appears to have received at least three or four tuns of wine annually, as tythe, from the produce of the vineyards in his diocese; and to have made frequent reservations in his leases of a certain quantity of wine for rent. A plot of land in London, which now forms East-Smithfield and some adjoining streets, was withheld from the religious house within Aldgate by four successive countesses of the Tower, in the reigns of Rufus, Henry, and Stephen, and made by them into a vineyard to their great emolument and profit. In the old accounts of rectorial and vicarial revenues, and in the old registers of ecclesiastical suits concerning them; the title of wine is an article that frequently occurs in Kent, Surry, and other counties. And the wines of Gloucestershire, within a century after the conquest, were little inferior to the French in sweetness. The beautiful region of Gaul, which had not a single vine in the days of Cæsar, had numbers so early as the time of Strabo. The south of it was particularly stocked with them; and they had even extended themselves into the interior parts of the country: But the grapes of the latter did not ripen kindly. And France was even famous for its vineyards in the reign of Vespasian, and even exported its wines into Italy. The whole province of Narbonne was then covered with vines: and the wine-merchants of the country were remarkable for all the knavish dexterity of our modern brewers, tinging it with smoke, colouring it (as was suspected) with herbs and noxious dyes, and even adulterating the taste and appearance with aloe. And, as our first vines would be transplanted from Gaul, so were in all probability those of the Allobroges in Franche Compté. These were peculiarly fitted for cold countries. They ripened even in the frosts of the advancing winter. And they were of the same colour, and seem to have been of the same species, as the black Mulcadinies of the present day, which have lately been tried in the island, I think, and found to be fittest for the climate. These were pretty certainly brought into Britain a little after vines had been carried over all the kingdoms of Gaul, and about the middle of the third century; when the numerous plantations had gradually spread over the face of the latter, and must naturally have continued their progress into the former.

The Romans, even nearly to the days of Lucullus, were very seldom able to regale themselves with wine. Very little was then raised in the compass of Italy. And the foreign wines were so dear, that they were rarely produced at an entertainment; and, when they were, each guest was indulged only with a single draught. But in the seventh century of Rome, as their conquests augmented the degree of their wealth, and enlarged the sphere of their luxury, wines became the object of particular attention. Many vaults were constructed, and good stocks of liquor deposited in them.

Vitiosus
||
Viverra.

them. And this naturally gave encouragement to the wines of the country. The Falernian rose immediately into great repute; and a variety of others, that of Florence among the rest, succeeded it about the close of the century. And the more westerly parts of the European continent were, at once, subjected to the arms and enriched with the vines of Italy.

But the scarcity of the native, and dearth of the foreign wines in that country, several ages before the conquest of Lancashire, had called out the spirit of invention, and occasioned the making of spurious wines. These were still continued by the Romans, and naturally taught to the Britons. And they were made of almost all the products of the orchard and garden, the pear, the apple, mulberry, service, and rose. Two of them, therefore, were those agreeable liquors which we still denominate *cyder* and *perry*. The latter would be called *pyrum* by the Romans, and is therefore called *perry* or *pear-water* by us. And the former assumed among the Romans the appellation of *sicera*, which was colloquially pronounced by them *sidera*, as the same pronunciation of it among the present Italians shows; and retains therefore the denomination of *cider* among ourselves.

VITREOUS HUMOUR *of the Eye*. See ANATOMY, n° 406, p.

VITRIFICATION, in chemistry, the conversion of a body into glass by means of fire. See GLASS.

VITRIOL, a compound imperfect salt, formed by the union of certain metals with the sulphureous acid. It is of three colours, white, blue, and green. See CHEMISTRY, n° 110. 142. 157.

VITRIOLATED, among chemists, something impregnated, or supposed to be so, with vitriol or its acid.

VITRIOLIC, an appellation given to whatever abounds with, or partakes of the nature of, vitriol: thus such fossil bodies as contain vitriol are called *vitriolic minerals*, or *ores of vitriol*.

VITRUVIUS POLLIO (Marcus), a very celebrated Roman architect, was, according to the common opinion, born at Verona, and lived in the reign of Augustus, to whom he dedicated his excellent treatise on architecture, divided into ten books. William Philander's edition of this celebrated work is esteemed. Claudius Perrault has given an excellent translation of it in French, with learned notes. There are also several English translations of Vitruvius.

VITUS'S DANCE. See MEDICINE, n° 391, and p. 470.

VIVERRA, the WEASEL: a genus of quadrupeds belonging to the order of feræ. They have six fore-teeth, the intermediate ones being shorter, and more than three grinders, and the claws are exerted. The species are,

1. The ichneumon, with the tail tapering to a point, and the toes distant from each other; inhabits Egypt, Barbary, India and its islands. It is there a most useful animal; being an inveterate enemy to the serpents and other noxious reptiles which infest the torrid zone: it attacks without dread that most fatal of serpents the Naja, or Cobra de Capello; and should it receive a wound in the combat, instantly retires, and is said to obtain an antidote from a certain herb; after which it returns to the attack, and seldom fails of

victory: it is a great destroyer of the eggs of crocodiles, which it digs out of the sand; and even kills multitudes of the young of those terrible reptiles: it was not therefore without reason, that the ancient Egyptians ranked the ichneumon among their deities. This animal is at present domesticated and kept in houses in India and in Egypt, for it is more useful than a cat, in destroying rats and mice; and grows very tame. It is very active; springs with great agility on its prey; will glide along the ground like a serpent, and seem as if without feet. It fits up like a squirrel, and eats with its fore-feet, catching any thing that is flung to it. It is a great enemy to poultry; and will feign itself dead, till they come within reach: loves fish; draws its prey, after sucking the blood, to its hole. Its excrements are very fetid; when it sleeps, it brings its head and tail under its belly, appearing like a round ball, with two legs sticking out. Rumphius observes how skillfully it seizes the serpents by the throat, so as to avoid receiving an injury; and Lucan beautifully describes the same address of this animal, in conquering the Egyptian asp.

*Aspidas ut Pharias cauda flectitur hostis
Ladit, et iratas incerta precevat umbras
Obliquansque caput vanas serpenti in auras
Effusa toto comprehendit gurgula morsu
Lacerat citra suum: tunc irritis postis
Exprimitur, faucibus suavi percutit veneno*

2. The yzquepatl, or flitting weasel, has a short slender nose; short ears and legs; black body, full of hair; the tail long, of a black and white colour; length from nose to tail, about eighteen inches. It inhabits Mexico, and perhaps other parts of America. This and some other species are remarkable for the pestiferous, suffocating, and most fetid vapour, they emit from behind, when attacked, pursued, or frightened: it is their only means of defence. Some turn their tail to their enemy, and keep them at a distance by a frequent creptus; and others ejaculate their urine, tainted with the horrid effluvia, to the distance of eighteen feet. The pursuers are stopped with the terrible stench. Should any of this liquor fall into the eyes, it almost occasions blindness: if on the cloaths, the smell will remain for several days, in spite of all washing; they must even be buried in fresh soil, in order to be sweetened. Dogs that are not true bred, run back as soon as they perceive the smell: those that have been used to it, will kill the animal; but are often obliged to relieve themselves by thrusting their noses into the ground. There is no bearing the company of a dog that has killed one, for several days. Professor Kalm was one night in great danger of being suffocated by one that was pursued into a house where he slept; and it affected the cattle so, that they bellowed through pain. Another, which was killed by a maid-servant in a cellar, so affected her with its stench, that she lay ill for several days; all the provisions that were in the place were so tainted, that the owner was obliged to throw them away. Notwithstanding this, the flesh is reckoned good meat, and not unlike that of a pig; but it must be skinned as soon as killed, and the bladder taken carefully out. The Virginian species is capable of being tamed, and will follow its master like a dog: it never emits its vapour, except terrified. It breeds in hollow trees, or holes under ground, or in clefts

Viverr

clefs of rocks; climbs trees with great agility; kills poultry; eats eggs, and destroys young birds.

Another species resembling this, inhabits Peru and other parts of South America; its pestilential vapour overcomes even the panther of America, and stupifies that formidable enemy.

3. The zibetha, or civet-cat, has short rounded ears; the back and sides cinereous, tinged with yellow, marked with large dusky spots disposed in rows; the hair coarse; that on the top of the body longest, standing up like a mane; the tail sometimes wholly black; sometimes spotted near the base; length, from nose to tail, about two feet three inches; the tail fourteen inches; the body pretty thick. It inhabits India, the Philippine isles, Guinea, Ethiopia, and Madagascar. The famous drug musk, or civet, is produced from an overture between the privities and the anus, in both sexes, secreted from certain glands. The persons who keep them procure the musk by scraping the inside of this bag twice a week with an iron spatula, and get about a dram each time: but it is seldom sold pure; being generally mixed with suet or oil, to make it more weighty. The males yield the milk; especially when they are previously irritated. They are fed, when young, with pap made of millet, with a little flesh or fish; when old, with raw flesh. In a wild state, they prey on fowl. These animals seem not to be known to the ancients: it is probable the drug was brought without their knowing its origin; for it is certain the fine gentlemen in Rome use perfume.

VIVES, in farriery. See there, § x.

VIVIPAROUS, in natural history, an epithet applied to such animals as bring forth their young alive and perfect; in contradistinction to them that lay eggs, which are called *oviparus* animals.

UKRAINE, a large country of Europe, bounded on the north by Poland and Muscovy, on the east by Muscovy, on the south by Tartary, and on the west by Moldavia. This province is one continued plain, interspersed with several fine rivers and agreeable forests. It is exceedingly fertile, and produces all the necessaries of life. The rivers swarm with all sorts of fish, and game is also very plenty. There are no brick buildings, all the houses being of wood after the Russian manner. It belongs to the Poles and Muscovites; but these last possess the greatest part. The people that now inhabit it are called *Chacks*.

ULCER, in surgery. See there, § iv. p. 849.

ULCER, farriery. See there, § xvi.

ULEX, *FURZE*, *GORSE*, or *WHINS*; a genus of the decandria order, belonging to the dadelphica class of plants. There are two species; of which the most remarkable is the *Europæus*, or common furze. This is so well known as to need no description. It is frequently cut to make faggots for heating ovens, which it does very soon, burning rapidly and with a great degree of heat. The ashes yield an alkaline salt. For its uses as a fence, and food for horses, see *AGRICULTURE*, n° 46. and *FENCE*.

ULIETEA, one of the Society islands. This island is about 21 leagues in circuit. Its productions are plantains, cocoa-nuts, yams, hogs, and fowl; the two latter of which are scarce. The soil on the top of one of the hills was found to be a kind of stone

Vol. X.

marle; on the sides were found some scattered flints, and a few small pieces of a cavernous or spongy stone lava, of a whitish colour, which seemed to contain some remains of iron, so that it may possibly be here lodged in the mountains in a great quantity. Nothing was seen on this island to distinguish either its inhabitants, or their manners, from the other neighbouring islands. The first Europeans who landed on this shore, were Mr Banks and Dr Solander; they were received by the natives in the most courteous manner, reports concerning them having been their harbingers from O-Taheitee. Every body seemed to fear and respect them, placing in them at the same time the utmost confidence; behaving, as if conscious, that their visitors possessed the power of doing them mischief without a disposition to make use of it.

ULIGINOUS, in agriculture, an appellation given to a moist, moorish, and fenny soil.

ULLAGE, in gauging, is so much of a cask or other vessel as it wants of being full.

ULM, a free and imperial city of Germany, in the circle of Swabia, seated on the river Iller. It is a pretty large place, defended by fortifications; and the inhabitants are protestants. Here the archives of the circle are deposited, and it carries on a very great trade. The elector of Bavaria became master of it, in 1702, by a stratagem; but, in 1604, the French being vanquished at the battle of Hochlter, the Bavarians surrendered it by capitulation. The Roman Catholics have but two churches, all the rest belonging to the Protestants. E. Long. 10. 5. N. Lat. 48. 30.

ULMUS, the *ELM*; a genus of the digynia order, belonging to the pentandria class of plants. There are six species; of which the most remarkable are, 1. The *campestria*, or common rough broad-leaved witch elm, is very common in the north-west counties of England, where it is generally believed to grow naturally in the woods; this grows to a very large size. The bark of the young branches is smooth and very tough, but that of the old trees cracks and is rough. The leaves are rough, and are doubly sawed on their edges. Their base is unequal, standing on short foot-stalks. The flowers come out in March upon slender twigs in clusters, of a deep red colour; and are succeeded by oval bordered capsules, containing one roundish compressed seed, which ripens in May. The wood of this tree is very good for all the purposes of any kind of elm, and the trees grow to a very large size; but as the leaves do not come out till late in the spring, there are few persons who plant these trees for ornament. 2. The *scaber*, or *witch-hazel*, grows naturally in some of the northern counties in England, where it has its name from the resemblance of the young shoots and leaves to those of hazel. This grows to a tree of great magnitude. The bark of the young shoots is very smooth and tough; it is of a yellowish brown colour, with spots of white. The flowers grow in clusters toward the end of the twigs; they have long leafy envelopments, of a green colour, appearing in the spring before their leaves, and the seeds ripen the latter end of May. The wood of this tree is not so good for use as that of the first sort. Formerly, when long bows were in use, many of them were made of the boughs of this tree. 3. The *fativa*, improperly called *English elm*, is not a native of Eng-

Ulms,
Ulster.

land, and is only found in plantations where the young trees were procured from the neighbourhood of London. Where this tree grows naturally, is not easy to determine; some persons have supposed it was brought from Germany. As this tree is well known, it requires no description. The flowers are of a purplish red colour, and generally appear the beginning of March, but Mr Miller says he could never observe any seed from this sort. 4. The glaber, or smooth-leaved witch-elm, is very common in several parts of Hertfordshire, Essex, and other north-east counties of England; this grows to a large tree, and is much esteemed. The branches spread out like those of the first sort. The leaves are sharply sawed on their edges; they are smoother than most of the other sorts: they do not appear till the middle or latter end of May, so the trees are seldom planted for ornament. 5. The minor, or upright elm, is found growing in hedge-rows in several parts of England. The branches of this sort have a smooth grayish bark, and grow erect. The leaves are narrow, and more pointed than those of the English elm, and are smoother; they are later in coming out in the spring than those, but continue longer in autumn; this has been by some called the *Irish elm*.

All the sorts of elm may be either propagated by layers or suckers taken from the roots of the old trees, the latter of which is generally practised by the nursery-gardeners: but as these are often cut up with indifferent roots, they often miscarry, and render the success doubtful; whereas those which are propagated by layers are in no hazard, and always make better roots and come on faster than the other, and do not send out suckers from their roots in such plenty, for which reason this method should be more universally practised.

ULSTER, the most northerly province of Ireland. In Latin it is called *Ulonia*, in Irish *Cui Guilly*; and gives the title of *earl* to the dukes of York of the royal family. It is bounded by the Atlantic Ocean on the west, St George's channel and the Irish Sea on the east, the Deucaledonian Ocean on the north, and on the south and south-west the provinces of Leinster and Connaught. Its greatest length is near 120 miles, its breadth about 100; and its circumference, including the windings and turnings, 460; containing 9 counties, 58 market-towns and boroughs, 1 archbishopric, 6 bishoprics, and 214 parishes. Ulster abounds in lakes and rivers, which supply it with variety of fine fish, especially salmon, besides what it has from the sea, with which a great part of it is bounded. The southern parts of it are rich, fertile, well cultivated, and inclosed; but the greater part of the northern is open and mountainous. The towns of this province are in general the neatest and best built of any in Ireland, as well as the farm-houses; which in most parts of the kingdom are constructed of no better materials than clay and straw. The inhabitants of Ulster are also more like the English in their manner and dialect, than those of the other three provinces: for as it includes within itself the whole, or by far the greater part of the linen manufactory, the best branch of trade in the kingdom, they have consequently the greatest intercourse with England. An Englishman in some parts of it, indeed, will imagine himself, from the similarity

of their language and manners, in his own country. This province had anciently petty kings of its own. It was first subjected to the English in the reign of Henry II. by John Courcy, the first who bore the title of *earl of Ulster*; but it afterwards threw off the yoke, and was never entirely reduced till the reign of James I. when great numbers of Scots by his encouragement went and settled in it. Of these, most of the present inhabitants are the descendants. This province was the first and principal scene of the bloody massacre in 1741. The counties contained in it are, Donegal, Londonderry, Antrim, Tyrone, Fermanagh, Cavan, Monaghan, Armagh, and Down.

ULTERIOR, in geography, is applied to some part of a county or province, which, with regard to the rest of that country, is situated on the farther side of the river, mountain, or other boundary, which separates the two countries.

ULTRAMARINE, a beautiful blue colour used by the painters, prepared from the lapis lazuli by calcination.

ULTRAJECTUM. See *TRAJECTUM Rheni*.

ULTRAMONTANE, something beyond the mountains. The term is principally applied in relation to France and Italy, which are separated by the Alps.

ULVA, LAVER, or *Turkey Feather*; a genus of the order of algae, belonging to the cryptogamia class of plants. It consists merely of a foliaceous substance formed into long cylindrical tubes. There are 10 species; of which the most remarkable are, 1. The umbilicalis, navel leaver, in Scotland called *flake* or *slake*, is frequent on sea-rocks, and sometimes on low shores, growing single. It is a wide membranaceous leaf, of a dark, dull, purple colour, expanded flat; for the most part in a circular form, variously sinuated on the edges; often perforated on the surface, and generally fixed to the rocks by a central root. The substance of it is smooth and shining, and a little tough, but not difficult to be torn. The breadth is from three inches to a foot. It often varies into a riband-like form. The inhabitants of the Western isles gather it in the month of March; and after pounding and stewing it with a little water, eat it with pepper, vinegar, and butter. Others stew it with leeks or onions. In England it is generally pickled with salt, and preserved in jars; and when brought to table is stewed, and eaten with oil and lemon-juice.

ULUG BEIG, a Persian prince and learned astronomer, was descended from the famous Tamerlane, and reigned at Samarcand about 40 years; after which he was murdered by his own son, in 1449. His catalogue of the fixed stars, rectified for the year 1434, was published at Oxford by Mr Hyde, in 1665, with learned notes. Mr Hudson printed in his English Geography *Ulug Beig's* Tables of the longitude and latitude of places; and Mr Graves published, in Latin, his *Astronomical Epochas*, at London, in 1650.

ULYSSES, king of Ithaca, the son of Laertius, and father of Telemachus, and one of those heroes who contributed most to the taking of Troy. After the destruction of that city, he wandered for 10 years; and at last returned to Ithaca, where, with the assistance of Telemachus, he killed Antinous and other princes who intended to marry his wife Penelope and seize his dominions. He at length resigned the government of the

Uterior
||
Ulysses.

Umbella
||
Uction.

the kingdom to his son Telémachus; and was killed by Telégonus, his son by Circe, who did not know him. This hero is the subject of the *Odyssey*.

UMBELLA, an **UMBEL**, in botany; a species of receptacle: or rather a mode of flowering, in which a number of slender foot-stalks proceed from the same centre, and rise to an equal height, so as to form an even, and generally round surface at top. The term differs from *corymbus*, another mode of flowering, in that there is a common party the point, to wit, from which issue all the foot-stalks; and in that the foot-stalks are of an equal length, whereas in a *corymbus* the foot-stalks proceed from different points, and though they altogether form an even surface at top, as in the umbel, yet is each lower foot-stalk of greater length than that immediately above it.

UMBELLATÆ, the name of a class in Ray's and Tournefort's methods, consisting of plants whose flowers grow in umbels, with five petals that are often unequal, and two naked seeds that are joined at top and separated below.

The same plants constitute the 45th order of Linnaeus's Fragments of a Natural Method. See **BOTANY**, p. 1315.

UMBELLIFEROUS PLANTS, are such as have their tops branched and spread out like an umbrella.

UMBILICAL, among anatomists, something relating to the umbilicus or navel.

UMPIRE, a third person chosen to decide a controversy left to arbitration.

UNCIA, in general, a Latin term denoting the twelfth part of any thing; particularly the twelfth part of a pound, called in English an *ounce*; or the twelfth part of a foot, called an *inch*.

UNCTION, the act of anointing or rubbing with oil or other fatty matter.

UNCTION, in matters of religion, is used for the character conferred on sacred things, by anointing them with oil. Unctions were very frequent among the Hebrews. They anointed both their kings and high-priests at the ceremony of their inauguration. They also anointed the sacred vessels of the tabernacle and temple, to sanctify and consecrate them to the service of God. The unction of kings is supposed to be a ceremony introduced very late among the Christian princes. It is said, that none of the emperors were ever anointed before Justinian, or Justin. The emperors of Germany took the practice from those of the eastern empire: king Pepin of France was the first who received the unction. In the ancient Christian church, unction always accompanied the ceremonies of baptism and confirmation. Extreme unction, or the anointing persons in the article of death, was also practised by the ancient Christians, in compliance with the precept of St James, chap. v. 14 and 15 verses; and this extreme unction the Romish church has advanced to the dignity of a sacrament. It is administered to none but such as are afflicted with some mortal disease, or are in a decrepit age. It is refused to impenitent persons, as also to criminals. The parts to be anointed are the eyes, the ears, the nostrils, the mouth, the hands, the feet, and the reins. The laity are anointed in the palms of the hands, but priests on the back of it; because the palms of their hands have been already consecrated by ordination. The parts above-mentioned

are anointed in the form of a cross. The priest begins anointing the sick person's eyes, saying, "May God, by his holy anointing, pardon you the sins you have committed by the eyes." In like manner he proceeds to the other parts, varying the words according to the parts he anoints.

UNDECAGON, is a regular polygon, of 11 sides.

UNDECEM VIR, a magistrate among the ancient Athenians, who had ten other colleagues or associates joined with him in the same commission. The functions of the undecemviri at Athens were much the same as those of the *prevoits de marcheausse* in France. They took care of the apprehending of criminals; secured them in the hands of justice; and when they were condemned, took them again into custody, that the sentence might be executed on them. They were chosen by the tribes, each tribe naming its own; and as the number of the tribes after Cullithenes was but ten, which made ten members, a scribe or notary was added, which made the number eleven.

UNDERSTANDING, is defined by the Peripatetics, to be a faculty of the reasonable soul, conversant about intelligible things, considered as intelligible. They also make it twofold, *viz.* active and passive. Active understanding, they hold that faculty of the soul by which the species and images of intelligible things are framed, on occasion of the presence of phantasms or appearances thereof. For maintaining the intellect to be material, they hold it impossible it should be disposed to think by any disproportionate phantasms of mere body, and therefore that it is obliged to frame other proportionate species of itself, and hence its denomination *active*. Passive understanding, is that which, receiving the species framed by the active understanding, breaks forth into actual knowledge.

The moderns set aside the Peripatetic notion of an active understanding. The Cartesian define the understanding to be that faculty whereby the mind conversing with, and as it were intent on, itself, evidently knows what is true in any thing not exceeding its capacity. The Corpuscular Philosophers define the understanding to be a faculty expressive of things which strike on the external senses, either by their images or their effects, and so enter the mind. Their great doctrine is, *Nihil est in intellectu quod non prius fuerit in sensu*; and to this doctrine Mr Locke, and most of the latest English philosophers, subscribe.

Between the Cartesian and Corpuscularians there is this farther difference, that the latter make the judgment to belong to the understanding, but the former to the will. Hence, according to the most approved opinions of the Corpuscularians, the understanding has two offices, *viz.* perception and judgment; according to the Cartesian, it has only one, *viz.* perception. See **METAPHYSICS** and **LOGIC**.

UNDERWALD, a canton of Switzerland, and the sixth in rank. It is bounded on the north by the canton of Lucern and by the Lake of the Four Cantons, on the east by the high mountains which separate it from the canton of Bern, and on the west by the Canton of Bern. It is divided into two great valleys, which are separated by a chain of mountains covered with forests. The religion of this canton is the Roman Catholic.

UNDERWOOD, is coppice, or any wood that is not accounted timber.

UNDULATION, in physics, a kind of tremulous motion or vibration observable in a liquid whereby it alternately rises and falls like the waves of the sea.

UNGUENT, in medicine and surgery, a topical remedy or composition, chiefly used in the dressing of wounds or blisters.

UNICORN, an animal famous among the ancients, and thought to be the same with the rhinoceros. See RHINOCEROS.

UNICORN *Fish*. See MONODON.

UNIFORM, denotes a thing to be similar, or consistent either with another thing, or with itself, in respect of figure, structure, proportion or the like; in which sense it stands opposed to difform.

UNIFORMITY, a similitude or resemblance between the parts of a whole.

UNIFORMITY and Variety. In things of nature's workmanship, whether we regard their internal or external structure, beauty and design are equally conspicuous. We shall begin with the outside of nature, as what first presents itself.

The figure of an organic body is generally regular. The trunk of a tree, its branches, and their ramifications, are nearly round, and form a series regularly decreasing from the trunk to the smallest fibre: uniformity is no where more remarkable than in the leaves, which, in the same species, have all the same colour, size, and shape; the seeds and fruits are all regular figures, approaching for the most part to the globular form. Hence a plant, especially of the larger kind, with its trunk, branches, foliage, and fruit, is a charming object.

In an animal, the trunk, which is much larger than the other parts, occupies a chief place. Its shape, like that of the stem of plants, is nearly round; a figure which of all is the most agreeable. Its two sides are precisely similar: several of the under parts go off in pairs; and the two individuals of each pair are accurately uniform. The single parts are placed in the middle; the limbs, bearing a certain proportion to the trunk, serve to support it, and to give it a proper elevation; upon one extremity are disposed the neck and head, in the direction of the trunk: the head being the chief part, possesses with great propriety the chief place. Hence the beauty of the whole figure is the result of many equal and proportional parts orderly disposed; and the smallest variation in number, equality, proportion, or order, never fails to produce a perception of deformity.

Nature in no particular seems more profuse of ornament, than in the beautiful colouring of her works. The flowers of plants, the furs of beasts, and the feathers of birds, vie with each other in the beauty of their colours, which in lustre as well as in harmony are beyond the power of imitation. Of all natural appearances, the colouring of the human face is the most exquisite; it is the strongest instance of the ineffable art of nature, in adapting and proportioning its colours to the magnitude, figure, and position of the parts. In a word, colour seems to live in nature only, and to languish under the finest touches of art.

When we examine the internal structure of a plant or animal, a wonderful subtlety of mechanism is dis-

played. Man, in his mechanical operations, is confined to the surface of bodies; but the operations of nature are exerted through the whole substance, so as to reach even the elementary parts. Thus the body of an animal and that of a plant are composed of certain great vessels; these of smaller; and these again of still smaller, without end, as far as we can discover. This power of diffusing mechanism through the most intimate parts is peculiar to nature; and distinguishes her operations most remarkably from every work of art. Such texture, continued from the grosser parts to the most minute, preserves all along the strictest regularity: the fibres of plants are a bundle of cylindric canals, lying in the same direction, and parallel or nearly parallel to each other: in some instances, a most accurate arrangement of parts is discovered, as in onions; formed of concentric coats, one within another to the very centre. An animal body is still more admirable in the disposition of its internal parts, and in their order and symmetry; there is not a bone, a muscle, a blood-vessel, a nerve, that hath not one corresponding to it on the opposite side; and the same order is carried through the most minute parts. The lungs are composed of two parts, which are disposed upon the sides of the thorax; and the kidneys, in a lower situation, have a position not less orderly. As to the parts that are single, the heart is advantageously situated near the middle: the liver, stomach, and spleen, are disposed in the upper region of the abdomen, about the same height; the bladder is placed in the middle of the body, as well as the intestinal canal, which fills the whole cavity with its convolutions.

The mechanical power of nature, not confined to small bodies, reacheth equally those of the greatest size; witness the bodies that compose the solar system, which, however large, are weighed, measured, and subjected to certain laws, with the utmost accuracy. Their places round the sun, with their distances, are determined by a precise rule, corresponding to their quantity of matter. The superior dignity of the central body, in respect of its bulk and lucid appearance, is suited to the place it occupies. The globular figure of these bodies, is not only in itself beautiful, but is above all others fitted for regular motion. Each planet revolves about its own axis in a given time; and each moves round the sun, in an orbit nearly circular, and in a time proportioned to its distance. Their velocities, directed by an established law, are perpetually changing by regular accelerations and retardations. In fine, the great variety of regular appearances, joined with the beauty of the system itself, cannot fail to produce the highest delight in every one who is sensible of design, power, or beauty.

Nature hath a wonderful power of connecting systems with each other, and of propagating that connection through all her works. Thus the constituent parts of a plant, the roots, the stem, the branches, the leaves, the fruit, are really different systems, united by a mutual dependence on each other: in an animal, the lymphatic and lacteal ducts, the blood-vessels and nerves, the muscles and glands, the bones and cartilages, the membranes and bowels, with the other organs, form distinct systems, which are united into one whole. There are at the same time other connections less intimate. Every plant is joined to the earth by its roots.

Uniformity roots; it requires rain and dews to furnish it with juices; and it requires heat to preserve these juices in fluidity and motion. Every animal by its gravity is connected with the earth; with the element in which it breathes; and with the sun, by deriving from it cherishing and enlivening heat. The earth furnisheth aliment to plants, these to animals, and these again to other animals, in a long train of dependence. That the earth is part of a greater system, comprehending many bodies mutually attracting each other, and gravitating all toward one common centre, is now thoroughly explored. Such a regular and uniform series of connections, propagated through so great a number of beings, and through such wide spaces, is wonderful; and our wonder must increase, when we observe these connections propagated from the minutest atoms to bodies of the most enormous size, and so widely diffused as that we can neither perceive their beginning nor their end. That these connections are not confined within our own planetary system, is certain; they are diffused over spaces still more remote, where new bodies and systems rise without end. All space is filled with the works of God, which are conducted by one plan, to answer unerringly one great end.

But the most wonderful connection of all, though not the most conspicuous, is that of our internal frame with the works of nature: man is obviously fitted for contemplating these works, because in this contemplation he has great delight. The works of nature are remarkable in their uniformity not less than in their variety; and the mind of man is fitted to receive pleasure equally from both. Uniformity and variety are interwoven in the works of nature with surprising art. Variety, however great, is never without some degree of uniformity; nor the greatest uniformity without some degree of variety. There is great variety in the same plant, by the different appearances of its stem, branches, leaves, blossoms, fruit, size, and colour; and yet when we trace that variety through different plants, especially of the same kind, there is discovered a surprising uniformity. Again, where nature seems to have intended the most exact uniformity, as among individuals of the same kind, there still appears a diversity, which serves readily to distinguish one individual from another. It is indeed admirable, that the human visage, in which uniformity is so prevalent, should yet be so marked, as to leave no room among millions for mistaking one person for another; these marks, though clearly perceived, are generally so delicate, that words cannot be found to describe them. A correspondence so perfect between the human mind and the works of nature is extremely remarkable. The opposition between variety and uniformity is so great, that one would not readily imagine they could both be relished by the same palate; at least not in the same object, nor at the same time: it is however true, that the pleasures they afford being happily adjusted to each other, and readily mixing in intimate union, are frequently produced by the same individual object. Nay, further, in the objects that touch us the most, uniformity and variety are constantly combined; witness natural objects, where this combination is always found in perfection. Hence it is, that natural objects readily form themselves into groups, and are agreeable in whatever manner combined: a wood with its trees, shrubs, and herbs, is agree-

able; the music of birds, the lowing of cattle, and the murmuring of a brook, are in conjunction delightful; though they strike the ear without modulation or harmony. In short, nothing can be more happily accommodated to the inward constitution of man, than that mixture of uniformity with variety which the eye discovers in natural objects; and accordingly the mind is never more highly gratified than in contemplating a natural landscape.

UNIFORMITY AND VARIETY, considered with relation to the fine arts.—In general, in every work of art, it must be agreeable to find that degree of variety which corresponds to the natural course of our perceptions; and that an excess in variety or in uniformity must be disagreeable, by varying that natural course. For that reason, works of art admit more or less variety according to the nature of the subject. In a picture of an interesting event, that strongly attaches the spectator to a single object, the mind relisheth not a multiplicity of figures nor of ornaments: a picture, again, representing a gay subject, admits great variety of figures and ornaments; because these are agreeable to the mind in a cheerful tone. The same observation is applicable to poetry and to music.

It must be at the same time remarked, that one can bear a greater variety of natural objects than of objects in a picture; and a greater variety in a picture, than in a description. A real object presented to view, makes an impression more readily than when represented in colours, and much more readily than when represented in words. Hence it is, that the profuse variety of objects in some natural landscapes neither breed confusion nor fatigue; and for the same reason, there is place for greater variety of ornament in a picture than in a poem. A picture however, like a building, ought to be so simple as to be comprehended in one view. Whether every one of Le Brun's pictures of Alexander's history will stand the test, is submitted to judges.

From these general observations we proceed to particulars. In works exposed continually to public view, variety ought to be studied. It is a rule, accordingly, in sculpture, to contrast the different limbs of a statue, in order to give it all the variety possible. Though the cone in a single view be more beautiful than the pyramid, yet a pyramidal steeple, because of its variety, is justly preferred. For the same reason, the oval is preferred before the circle; and painters, in copying buildings or any regular works, give an air of variety by representing the subject in an angular view; we are pleased with the variety, without losing sight of the regularity. In a landscape representing animals, those especially of the same kind, contrast ought to prevail: to draw one sleeping, another awake; one sitting, another in motion; one moving toward the spectator, another from him, is the life of such a performance.

In every sort of writing intended for amusement, variety is necessary in proportion to the length of the work. Want of variety is sensibly felt in Davila's history of the Civil Wars of France: the events are indeed important and various; but the reader languishes by a tiresome monotony of character, every person engaged being figured a consummate politician, governed by interest only. It is hard to say, whether Ovid disgusts more by too great variety, or too great uniformity.

mony. His stories are all of the same kind, concluding invariably with the transformation of one being into another; and so far he is tiresome by excess in uniformity. He is not less fatiguing by excess in variety, hurrying his reader incessantly from story to story. Aristotle is still more fatiguing than Ovid, by exceeding the just bounds of variety. Not satisfied, like Ovid, with a succession in his stories, he distracts the reader, by jumbling together a multitude of them without any connection. Nor is the Orlando Furioso less tiresome by its uniformity than the Metamorphoses, though in a different manner. After a story is brought to a crisis, the reader, intent on the catastrophe, is suddenly snatched away to a new story, which makes no impression so long as the mind is occupied with the former. This tantalizing method, from which the author never once swerves during the course of a long work, beside its uniformity, hath another bad effect; it prevents that sympathy which is raised by an interesting event when the reader meets with no interruption.

It may surprise some readers to find variety treated as only contributing to make a train of perceptions pleasant, when it is commonly held to be a necessary ingredient in beauty of whatever kind; according to the definition, "That beauty consists in uniformity amid variety." But this definition, however applicable to one or other species, is far from being just with respect to beauty in general. Variety contributes no share to the beauty of a moral action, nor of a mathematical theorem; and numberless are the beautiful objects of sight that have little or no variety in them: a globe, the most uniform of all figures, is of all the most beautiful; and a square, though more beautiful than a trapezium, hath less variety in its constituent parts. The foregoing definition, which at best is but obscurely expressed, is only applicable to a number of objects in a group or in succession; among which, indeed, a due mixture of uniformity and variety is always agreeable; provided the particular objects separately considered, be in any degree beautiful; for uniformity amid variety among ugly objects affords no pleasure. This circumstance is totally omitted in the definition; and indeed to have mentioned it, would at the very first glance have shown the definition to be imperfect: for to define beauty as arising from beautiful objects blended together in a due proportion of uniformity and variety, would be too gross to pass current; as nothing can be more gross, than to employ in a definition the very term that is to be explained.

UNION, a junction, coalition, or assemblage of two or more different things in one.

UNION, or *The Union*, by way of eminence, is more particularly used to express the act by which the two separate kingdoms of England and Scotland were incorporated into one, under the title of *The kingdom of Great Britain*. This union, in vain attempted by king James I. was at length effected in the year 1707, 6 Annæ; when twenty-five articles were agreed to by the parliament of both nations, the purport of the most considerable being as follow:

1. That on the first of May 1707, and for ever after, the kingdoms of England and Scotland shall be united into one kingdom, by the name of *Great Britain*.

2. The succession to the monarchy of Great Britain

shall be the same as was before settled with regard to that of England.

3. The united kingdom shall be represented by one parliament.

4. There shall be a communication of all rights and privileges between the subjects of both kingdoms, except where it is otherwise agreed.

9. When England raises 2,000,000*l.* by a land tax, Scotland shall raise 48,000*l.*

16, 17. The standards of the coin, of weights, and of measures, shall be reduced to those of England, throughout the united kingdoms.

18. The laws relating to trade, customs, and the excise, shall be the same in Scotland as in England. But all the other laws of Scotland shall remain in force; but alterable by the parliament of Great Britain. Yet with this caution, that laws relating to public policy are alterable at the discretion of the parliament; laws relating to private right are not to be altered but for the evident utility of the people of Scotland.

22. Sixteen peers are to be chosen to represent the peerage of Scotland in parliament, and 45 members to sit in the house of commons.

23. The 16 peers of Scotland shall have all privileges of parliament; and all peers of Scotland shall be peers of Great Britain, and rank next after those of the same degree at the time of the union, and shall have all privileges of peers, except sitting in the house of lords and voting on the trial of a peer.

These are the principal of the 25 articles of union, which are ratified and confirmed by statute 5 Ann. c. 8. in which statute there are also two acts of parliament recited; the one of Scotland, whereby the church of Scotland, and also the four universities of that kingdom, are established for ever, and all succeeding sovereigns are to take an oath inviolably to maintain the same; the other of England, 5 Annæ, c. 6. whereby the acts of uniformity of 13 Eliz. and 13 Car. II. (except as the same had been altered by parliament at that time) and all other acts then in force for the preservation of the church of England, are declared perpetual; and it is stipulated, that every subsequent king and queen shall take an oath inviolably to maintain the same within England, Ireland, Wales, and the town of Berwick upon Tweed. And it is enacted, that these two acts "shall for ever be observed as fundamental and essential conditions of the union."

Upon these articles and act of union, it is to be observed, 1. That the two kingdoms are now so inseparably united, that nothing can ever disunite them; except the mutual consent of both, or the successful resistance of either, upon apprehending an infringement of those points which, when they were separate and independent nations, it was mutually stipulated should be "fundamental and essential conditions of the union." 2. That whatever else may be deemed "fundamental and essential conditions," the preservation of the two churches, of England and Scotland, in the same state that they were in at the time of the union, and the maintenance of the acts of uniformity which establish the liturgy, are expressly declared so to be. 3. That therefore any alteration in the constitution of either of those churches, or in the liturgy of the church of England, (unless with the consent of the respective churches,

Union
of
United
Provinces.

churches, collectively or representatively given) would be an infringement of these "fundamental and essential conditions," and greatly endanger the union.

4. That the municipal laws of Scotland are ordained to be still observed in that part of the island, unless altered by parliament; and as the parliament has not yet thought proper, except in a few instances, to alter them, they still (with regard to the particulars unaltered) continue in full force.

UNISON, in music. See INTERVAL.

UNIT, or UNITY, in arithmetic, the number one; or one single individual part of discrete quantity.

UNITED PROVINCES, or UNITED *Netherlands*, otherwise called the *Republic of Holland*, consist of the seven provinces of Holland, Zealand, Friesland, Groningen, Overijssel, Zulpfen, and Utrecht. They are bounded on the west by the German Ocean; on the east by the circle of Westphalia; and on the south by Flanders, Brabant, and the duchy of Cleves. They compose the greatest part of the ancient Batavia, whose inhabitants were formerly so much renowned for their valour. Under the Romans, they were exempt from imposts and taxes, in consequence of bearing the honourable title of *allies of the Republic*. On the decline of the Roman empire they fell under the power of the Turks; but on the decline of the house of Charlemagne, the great lords and officers of the crown taking advantage of the weakness of the princes, rendered their governments hereditary in their families. The United Provinces, and indeed the whole of the Netherlands, now experienced frequent revolutions; being sometimes united into a monarchy, sometimes governed by independent petty sovereigns. The history of these times affords only an account of wars of the different provinces with each other, which at last terminated in nothing, and which for that reason we pass over in silence. The Netherlands came into the possession of the house of Austria by the marriage of Mary of Burgundy with the emperor Maximilian; but on that prince's resigning the Imperial crown, in hopes of being made a pope, the 17 provinces of the Netherlands devolved of right on Don John of Spain; but he, and his successor Philip le Beau, dying in a short time after, they, in 1505, fell under the dominion of Charles V. at that time a minor.

At this period the seven provinces, which now composed the Republic of Holland, enjoyed a kind of independence; but the policy and warlike disposition of Charles soon reduced them to obedience. When he resigned the sceptre to his son Philip, the Low Countries were in a most flourishing condition. In this small tract of country were reckoned no fewer than 350 large cities inclosed with walls, and 6300 considerable towns, all become rich by their application to the arts and to commerce. At the same time the love of liberty was very prevalent among the inhabitants, and they were jealous of every invasion of their rights and privileges. The arbitrary government of Philip was therefore very disagreeable to his subjects in the Low Countries, and the partiality shown on all occasions to the Spaniards soon lost their affections altogether.

The extreme superstition, however, and cruel bigotry, of Philip, proved the greatest source of discontent. The doctrines of the reformers had been preached and

received with avidity in the Low Countries. A cruel persecution of the reformed had been commenced by Charles V. inasmuch that he is said to have destroyed no fewer than 100,000 persons on account of religion. This cruelty had no effect except to increase the number of heretics; which being observed by Mary queen of Hungary, sister to the emperor, she invited him to the Low Countries, that he might personally behold the bad effects of his cruelty. On this the emperor granted a toleration, but Philip was altogether inflexible. In order to proceed more effectually against the reformed, a court of inquisition was instituted; and under pretence that the three bishoprics, which at that time comprehended the whole country, were too large, seventeen of these dignitaries were erected, three with the title of archbishops. To afford sufficient revenues for these, it became necessary to suppress several abbeyes, which of itself produced great discontent. But what gave the finishing stroke to the whole was Philip's announcing his intention of residing constantly in Spain; his appointing the dukes of Parma, his natural sister, to be regent of the Netherlands; and giving her for a counsellor cardinal Granvele, a bloody persecutor of the reformed; at the same time that the provinces were oppressed by the violences of foreign troops, for the payment of whom they were also oppressed by taxes. Three councils were established at Brussels; one to preside over the laws and courts of justice; a second to direct every thing respecting peace or war; and the third to manage the revenues: but still the duchess of Parma was ordered to consult Granvele in every matter, and make him at all times her chief confidant.

The duchess took upon her the government of the Universal Low Countries in the year 1560; and was no sooner arrived at Brussels, than complaints poured in from all quarters against the inquisition, cardinal Granvele, and the new bishoprics. The duchess endeavoured to allay the ferment by fair words, but in vain. At the head of the malcontents were the prince of Orange, count Egmont, and count Horn, who strenuously insisted on calling an assembly of the States-general, and laying before them the grievances by which the country was oppressed. The event was, that, in 1564, the cardinal was obliged to resign his dignity; which yet did not produce any good effect, as he was succeeded by two of his creatures Barlaumont and Viglius, who trod exactly in his footsteps. They pushed on the inquisition to fresh executions; stigmatized the principal nobility as heretics; and on all occasions showed such violent and intolerable zeal for the Catholic religion, that one of Philip's ministers represented to him the danger there was of a total revolt of the provinces unless the rigours of persecution were somewhat relaxed. But Philip no sooner received this intelligence, than he replied, "that he had rather be without subjects, than be a king of heretics." Agreeable to this reply, all the obnoxious decrees were enforced with double rigour; upon which the state of affairs became so alarming, that it was thought necessary to send count Egmont into Spain, in order to have a personal interview with the king on the subject. Philip, accustomed to deceit, gave a smooth answer, abated the rigour of his decrees, and ordered the governor sometimes to consult with the prince of Orange.

Thus tranquillity was for a time restored; but in the year 1566, it being discovered that a scheme for the total extirpation of the Protestants had been concerted by the queen-mother of France, her son Charles IX. and Isabella queen of Spain, in a conference at Bayonne, matters became worse than ever. That the information received concerning this detestable combination was true, very soon appeared from Philip's disclaiming all the favourable interpretations which had been put upon his answer to count Egmont, and from his ordering the inquisition to proceed with more fury than ever. The consequence of this was, a general association against this abominable tribunal, which was subscribed by all orders and degrees of men, Roman Catholics as well as Protestants. The confederates, headed by Henry de Brodenrode, a descendant of the ancient earls of Holland, waited on the dukes of Parma, in such a formidable body, that she was obliged to dismiss them with an absolute promise that their demands should be granted. These demands were, that the inquisition should be abolished, and the edicts against liberty of conscience recalled; and for this he immediately interposed all her interest with Philip. Sir William Temple alleges, that Philip, in consequence of the governante's remonstrances, granted all that was desired, but too late. All other historians, however, agree that he was inflexible, and that the dukes could procure no better conditions than that heretics should from that time forward be hanged instead of being burned. Even this appeared a concession unworthy of the king; the royal name was therefore forbid to be used.

Before the confederates proceeded to extremities, they sent deputies to Madrid; but, according to some authors, they were refused admittance into the king's presence. It appears, however, that they had found means of representing the true state of affairs to the king, and of informing him that the disturbances proceeded from the detestation in which the inquisition was every where held in the Low Countries. Their representations produced no other effect than an equivocal promise, which was evidently never intended to be kept.

The governante received orders to proceed against heretics with the utmost severity; upon which the people broke out into acts of open rebellion. In several towns of Flanders the churches were destroyed, images pulled down, and all those acts of violence committed which are the usual operations of a lawless mob. The principal inhabitants, however, still remained quiet, and even did all in their power to restrain the violence of the commonalty; so that, had Philip made any kind of reasonable concession, the public tranquillity might have been restored. Instead of this, however, a new oath of allegiance was administered by the governante, and all persons were obliged to swear that they would regard as traitors and enemies to their country all whom the king should think proper to proscribe. This extraordinary proceeding was followed by the most cruel persecution that can be imagined; at the same time that the duke of Alva was sent into the Netherlands with an army of 10,000 veteran troops, to put the last hand to the misery of the people, and fully to establish the despotism of the court. Counts Egmont and Horn took the abovementioned oath; but the prince of Orange could by no means be induced to it, and

therefore retired into Germany, along with counts Brodenrode and Hoogftrere. Their example was followed by great numbers of all ranks and conditions; and after the arrival of the army commanded by the duke of Alva, such multitudes continued to emigrate, that the dukes of Parma informed the king, that within a few days, 100,000 families had left his dominions; that in a short time the country must be depopulated, in which case there would be no occasion for a governante: she therefore begged leave to resign before she should have the mortification and disgrace of being left alone in the Netherlands.

Philip immediately complied with the request of the prince, and the duke of Alva was appointed to succeed her in the government. It may easily be imagined that the miseries of the people would now become intolerable. The king was a proud and merciless tyrant, set at too great a distance from his subjects to be thoroughly sensible of their calamities, and totally destitute of compassion had he known them ever so well. The new governor was of the same disposition; and the army he commanded was fierce, rapacious, and cruel, desiring nothing more ardently than to enrich themselves at the expence of the inhabitants. The whole country was filled with blood and horror; counts Egmont and Horn were ignominiously executed, and the estate of the prince of Orange was confiscated. These last proceedings drove the people into despair, and they invited the prince to return, in order to take upon him the defence of the country from such insufferable tyranny and oppression.

All this time the prince of Orange, and his brother Lewis of Nassau, had been labouring to form alliances for the defence of the liberties of his country. He had represented matters in such a light to the emperor Maximilian, that his Imperial majesty sent an ambassador to Philip exhorting him to treat his subjects in the Netherlands with less rigour. This embassy was laughably received; Philip continued his persecutions, and the Prince of Orange his preparations for entering the Low Countries. His first efforts, however, were very unsuccessful. A detachment of Germans in the service of the prince attempted to penetrate into Brabant, and surprised Burmoed; but were defeated by a detachment from the duke of Alva's army. Another party, consisting chiefly of French, attempted to penetrate into Artois by the way of Picardy; but their officers were arrested by order of Charles IX. Lewis of Nassau, however, defeated a body of Spaniards, and killed 600 of them on the spot; but the vigilance of his enemies prevented him from drawing any advantage of consequence from his victory.

The duke of Alva was so much chagrined at the defeat sustained by his party, that he instantly assembled his troops from all quarters. His army then appeared too formidable to be opposed, and the prince of Nassau with count Hoogftrere retired towards the river Ens. But being hard pushed by the duke of Alva, and mutinies arising among their troops for want of pay, they were soon brought to an action, and totally defeated. The infantry were entirely cut in pieces; the cavalry were saved, but all the baggage and artillery were taken by the enemy. In the mean time the prince of Orange was hastening to the relief

relief of his distressed allies with an army of 28,000 men; but having the misfortune of being also defeated, and count Hoogstrate killed in the action, his soldiers deserted in such crowds, that he was at last obliged to disband his army and return to Germany.

This disaster happened in the year 1569. The duke of Alva resolved to make the most of his time. He entered Brussels in triumph; and let loose his vengeance against all who had in the least assisted, or been supposed to assist, the prince of Orange. All the prisoners taken in the last campaign were put to death; and, not content with this barbarity, the cruel governor projected nothing less than the total extirpation of the reformed religion, by the destruction of every one who professed it; and of rendering himself despotic, by erecting citadels in all the considerable towns which were to be garrisoned by his soldiers. He began with Amsterdam, in which he laid the foundations of a strong citadel. The people complained of it as an infringement of their rights, but the duke was deaf to their complaints. At Antwerp he caused his statue to be erected; and here he was figured treading on the necks of two smaller statues, which represented the two estates of the Low Countries. This piece of insolent vanity exasperated the people to a great degree; and they were still farther provoked by a demand of the hundredth part of every man's estate to be paid immediately for the support of the army, besides the tenth of all the merchandize, and the twentieth of all immoveables, to be annually levied as a standing revenue. The provinces remonstrated, and refused to submit to such intolerable exactions: the governor was inflexible; and being incensed at their resistance, he sent the regiment of Lombardy to live at free quarters in the province of Utrecht.

21
Privateers
sailed out

22
Duke of
Alva at-
tempts in
vain to effea-
ce his
new taxes
at Brussels.

In this situation of affairs, the prince of Orange was advised by admiral Coligni to fit out a squadron of privateers to cruise upon the Spaniards, intercept the supplies of money sent to the Netherlands, and thus raise a fund for the maintenance of an army. This measure was immediately executed, and numbers of the Spanish merchantmen were taken; but as no method was taken to save the profits, the designs of the prince of Orange were at first but little forwarded. The shoal of privateers went by the general name of *gueux*, or *sea-beggars*; and in a little time commenced pirates, to the no small detriment of their own country as well as the enemy.

23
Briel taken
by the Orange
party.

All this time the prince of Orange was employed in laying plans for the deliverance of his distressed country; but, in 1501, the duke of Alva, growing impatient, ordered the edict concerning the new taxes to be published at Brussels. The city was instantly filled with confusion; the soldiers seized on the goods of the inhabitants by force; tradesmen shut up their shops; and the peasants refused to bring provisions to the market. The states offered to pay a subsidy of 2,000,000 of florins annually in lieu of the intended tax; but their offer was rejected. The drum beat to arms, and orders were issued to hang all who refused to comply. The soldiers were preparing to obey, when news arrived of the surrender of Briel in the island of Voorn, at the entrance of the Meuse, to the Gueux. Lumey, who commanded the Orange squadron, made a descent on the island from 40 ships,

destroyed the churches, broke the images, and executed the priests, but offered no violence to the other inhabitants.

24
Duke of
Alva desists
from enforcing
his
taxes.

However unimportant the conquest of so inconsiderable a place might appear, it alarmed the duke of Alva, and produced the most extravagant rejoicings in Brussels. The duke regarding it as the harbinger of further opposition, dropped his taxes and executions for the present, and diligently applied himself to suppress the growing spirit of rebellion. He withdrew the garrison from Brussels, and detached it under the command of Maximilian Hermin Bossu, against the

25
A party of
his forces

the Gueux.

Gueux. This officer, endeavouring to force Briel, was defeated by the Orange faction, and forced to retire with loss to the island of Beyerland. Trifling as this victory might seem, it served to animate the depressed spirits of the enemies to the government. The prince of Orange, sensible of the advantage of possessing this island, exhorted the nobility of his party to fortify

26
The Gueux
take Delfshaven.

and garrison it; his orders were obeyed, by which means he soon became master of Delfshaven, a town situated on the opposite banks of the Meuse. It appeared in Bossu's retreat, how unpopular the duke of Alva was in every part of the country. Dordrecht shut its gates against him. Rotterdam refused to admit his troops; but Bossu obtaining permission that they should pass through in separate small divisions, seized the gates, and began a general massacre of the inhabitants. Four hundred souls perished by the sword, the town was pillaged, the women were ravished, and every possible act of barbarity and inhumanity committed. Retribution was soon made by the enemy. Alva had detached Ossorio d'Angulo with a body of forces to secure Flushing, a considerable port in Zealand, and to erect a citadel. The inhabitants denied

27
Inhabitants
of Rotterdam
massacred
by the
Spaniards.

Ossorio admittance, shut their gates, and seized Pacanco, a famous engineer, who had come to measure the ground where the citadel was to be erected. Apprehending that attempts would be made to force them to submission, they petitioned Lumey, admiral of the Gueux, for assistance; and he furnished them with 200 men, under the command of Captain Treslong. On the arrival of this reinforcement, the Spanish engineer was hanged, and an unsuccessful attempt made to surprise Middleburg, the capital of the island of Walcheren. Not dispirited by this disappointment, the Zealanders assiduously prosecuted their cruizes upon the Spaniards, and obtained as much wealth as purchased a large store of arms and ammunition at Antwerp. Joined by great numbers of English and Scotch adventurers, they ventured to attack the duke of Medina Celi, sent with a strong squadron to succeed the duke of Alva in the government of the Ne-

at sea.

therlands. The duke was completely defeated, a great number of his ships were taken, and a booty amounting to near 1,000,000 livres was carried off by the Zealanders.

The duke of Alva now ordered a squadron of ships to be equipped at Amsterdam to bridle the insolence of Lumey and the Zealanders, while he busied himself in raising an army to oppose the prince of Orange and Lewis de Nassau, who were making great preparations in Germany and France. To augment the army in the field, he had draughted most of the garrisons. By this means the prince's friends gained pos-

cession of North Holland; and Lewis de Nassau was projecting a scheme to surprise Mons, with the inhabitants of which he held a secret correspondence. The design succeeded, which emboldened most of the cities and towns in Holland to declare against the government. The count de Bergues gained over several cities in Overysil, Guelderland, and Friseland. In a word, the revolt became so general, that the duke of Alva soon found he could not long resist the torrent. He now, when too late, published an edict to appease the people, setting forth, that he would consent to remit the most oppressive taxes, if the states could suggest any other means of raising the necessary supplies. He convoked the states-general to meet at the Hague, but his orders were now disregarded; and the states, in contempt of his authority, assembled at Dordrecht, inviting deputies from the prince of Orange, the nobility, and the towns that had declared against the governor. Here money was raised to enable the prince of Orange to begin his march. His forces amounted to 15,000 foot and 7000 horse. He had promised to advance three months pay; and was enabled to perform his engagements, by the liberality and public spirit of the states-general and the cities. Several regulations respecting the future support and government of the army were made on this occasion, and their proportions of the public expence assigned to the several provinces and cities. It was further resolved, that nothing of importance should be transacted without the privity and consent of the prince of Orange; and that the prince, on his part, should not negotiate a peace with the king or his lieutenants, contrary to the sentiments of the states. In a word, the prince showed the address with which he could manage and direct the people. Without the name of sovereign of the provinces under his government, he possessed the authority. He presided at all military operations by sea and land; made and disposed of offices at pleasure; assembled the states; and published all ordinances and regulations, relative to the present state of affairs, without controul. However, he conducted matters with the utmost delicacy, and used his power with great moderation, to avoid giving offence to the free spirit of the Hollanders. The Popish religion was banished the churches, and persons of that persuasion were, with great caution, admitted into public employments. Not only the king's revenue and church-tythes were appropriated to the public service, but the estates of those who remained firm in their loyalty. In short, the most vigorous measures were taken for resisting the tyranny of Spain; and those persons who had refused the tythes to the government, voluntarily subscribed their all to support a party formed in defence of liberty.

While the states-general were employed in ways and means to maintain an army, the prince of Orange advanced to Ruremonde, which he took by assault, on the refusal of the city to supply him with necessaries. From thence he marched to Brabant, and raised heavy contributions. He took Mechlin, Oudenarde, and Dendermonde; and could not restrain the excesses of the soldiers, who pillaged the churches, massacred the priests, and committed other barbarities. Next he approached to Mons, besieged by the duke of Alva, with design, if possible, to engage him to

give battle. The duke baffled all his endeavours to force him, and carried Mons by capitulation. The whole Spanish dominion, however, lately so insolent and exulting, was ready to expire in the Netherlands, had it not been revived by the massacre of the Protestants in Paris.

While the fate of Mons was depending, the states of Holland met at Haarlem, to deliberate on the defence of the province and the prosecution of the war. Amsterdam was in the enemy's hands, which greatly obstructed all their measures. It was therefore determined to besiege it; and the enterprise was committed to Lumey, chief of the Gueux. After putting the states to considerable expence, the project miscarried through Lumey's misconduct. Water was his element, but his vanity led him to display his abilities as a land-officer. He made regular approaches, and was foiled in every attempt.

The reduction of Mons, and the depression of spirits consequent on the massacre at Paris, obliged the prince of Orange to retire to Holland, and encouraged Alva to invest Dendermonde, Oudenarde, and Mechlin. The latter, being in no condition to resist, opened its gates; but the Spanish soldiers chose to scale the walls, to give an air of assault to the enterprise, and countenance to the horrid barbarities intended. Protestants and Catholics were massacred without distinction. The town was pillaged, and the booty estimated at 400,000 florins. All the other towns were evacuated by the garrisons, and loaded with heavy impositions by Alva. As to the prince, he had now removed the seat of war into the province of Holland. Only this province and Zealand remained firm to their engagements; the rest, overwhelmed with consternation, capitulated on the best terms they could procure from the government. However, the country being strong by its nature and situation among the waters, and more so by a fierce, rough, and sturdy people, proud of their ancient fame, and the most implacable enemies of Spanish tyranny, it was determined to make the most vigorous resistance. Frederic de Toledo was dispatched by Alva to begin the operations in Holland. He had already reduced Zutphen and Guelderland; and, flushed with success, appeared before Waerden, which he summoned to admit a garrison. The burghers replied, that they were intrusted by the king with the defence of the place, and could not receive a military force without violence to their privileges and engagements. They soon had reason to repent their firmness: the town was taken by surprise; and all the burghers, assembled in the great church to take the oaths of fidelity to the king, were wantonly butchered. Infants, old men, women, and the sick, were all put to the sword, without pity or remorse; and of all the barbarities hitherto committed, this was the most horrible. It was imagined that the terror inspired by such instances of severity, would reduce the people to obedience, and shake the obduracy of the other towns. The contrary effects were produced; rage and despair took possession of every breast, and all determined to suffer the last extremities rather than submit to so cruel a tyranny.

Having finished this tragedy, Frederic went to Amsterdam, to deliberate with the officers of the army about the siege of Haarlem. Here it was determined, before

Provinces.

before they proceeded to extremities; that the city of Amsterdam should write to the magistrates, exhorting them, in the most pathetic terms, to submit, rather than incur the punishment inflicted on Waerden. The council of Haarlem met to take this letter into consideration. Some were for soliciting an immediate reinforcement from the prince of Orange; and others, who apprehended the prince was too weak to afford the necessary relief, were for making the best terms possible with the king. Those of the latter opinion were the magistrates. Accordingly, without consulting the burghers, deputies were dispatched to Frederic to stipulate conditions. In their absence, Ripperda, a gentleman of Friseland, strongly attached to the prince of Orange and the cause of liberty, assembled the chief burghers; and so animated them against the Spaniards, that they resolved to stand a siege, and suffer all the horrors of war, rather than submit. They sent to the prince of Orange to acquaint him with their determination, and to implore assistance. Four companies of Germans were detached to reinforce the garrison of Haarlem; and the deputies, on their return, were seized as traitors to their country, sent to the prince of Orange, and by his order beheaded. Frederic was preparing to compel the burghers to submission. On the 19th of December, he invested the town, after carrying Sparendam fort by assault, with great loss and slaughter of his soldiers. A variety of errors were committed in the attack, in the defence, and manner of succouring Haarlem. The assailants and defendants had equally shown themselves ignorant of the art of war, and implacable in their resentment. The prince of Orange used every expedient to relieve to town; but all his attempts were frustrated by untoward accidents, and the vigilance of the Spaniards. At last, quite spent with fatigue, despairing of relief, weakened by losses, and totally exhausted of provisions and ammunition, the burghers of Haarlem surrendered upon more favourable terms than they could well expect. A few only of the most obstinate were executed; the rest were pardoned on taking an oath of fidelity, and paying an acknowledgment of 15,000 florins.

35
Haarlem
besieged.

36
And taken.

37
Successful of
the Zea-
landers by
sea.

During the siege of Haarlem, the Zealanders were performing glorious achievements by sea, and gaining victories over the Spanish naval armaments. All the efforts of the governor of Antwerp could not prevent their carrying off a great number of ships out of the harbour. To revenge the insult, and relieve Middleburg and Rammekins blocked up by the Zealanders, he equipped a squadron, and gave battle to Wertz, the Zealand admiral, but was defeated. After repairing and augmenting his fleet, he again set sail with sixty large vessels, encountered a squadron of Zealanders much inferior in strength, and met with his former fortune. Most of his ships were sunk or taken; but he found means to push into Middleburg, with the broken remains of his squadron, to the great joy of the garrison, now reduced by the scarcity of provisions to the last extremity. D'Avila's disgrace did not end here; for, on his return to Antwerp, he was a third time attacked and defeated, with considerable loss, by Wertz, who thus repaired the disappointment of an unsuccessful attempt made on Tolon.

Soon after the reduction of Haarlem, Alva, per-

ceiving that his severity answered no other purpose than irritating the people more against the Spanish government, published a proclamation, couched in the most soothing terms: but the people were not disposed to confide in promises so often violated, nor to throw themselves on the clemency of a prince and governor, who had shown themselves inflexible, implacable, perfidious, and inhuman. They now expected the worst that could happen, and bid defiance to fortune. The Spaniards were preparing to invest Almar, and the Hollanders put every means in practice to resist them. Eight months pay was due to the garrison, who began to mutiny; but contributions were raised, which silenced their clamours. Frederic of Toledo, with 16,000 men, sat down before a town fortified by no regular works, and defended only by 300 burghers, and 800 soldiers, in extreme want of provisions, and without the prospect of relief. Sonoï, the governor, despairing of being able to sustain a siege, wrote to the prince of Orange, that a place destitute of troops, provisions, ammunition, money, and every necessary, ought to be evacuated, and the few soldiers in garrison, and the burghers, saved from falling into the hands of the enemy. But the prince of Orange so animated them by a letter, that, to a man, the townsmen, governor, and soldiers, determined to sacrifice their lives, and spill the last drop of their blood in the breach. Perseverance had made the Zealanders masters of Rammekins, contrary to all hope and probability; the same virtue, the prince observed, might save Almar, a town of the utmost consequence to the cause of liberty. What particularly inspired the defendants with courage, was the prince's good fortune in surprising Gertrudenburg. Frederic pushed the siege with great vigour. He ordered the inhabitants of Haarlem to work in the trenches, and sustain the first fire of their friends and countrymen. On the 18th of September, a battery of 20 pieces of heavy cannon began to play; a breach was soon effected; the assault was given, and repulsed with vigour, though sustained by the bulk of the Spanish army. From a Spanish officer taken, the garrison were informed, that Alva had given orders to retire, in case he failed in the third assault; but if he succeeded, to put all to the sword. Their courage was whetted by this account, and preparations were cheerfully made for withstanding the utmost efforts. Frederic was foiled in every attempt; the assailants were driven from the breach with prodigious slaughter; the Spanish soldiers refused to mount the walls; in a word, the siege was raised, and the town relieved, to the exceeding joy of the prince of Orange, and great mortification of Alva.

This advantage was attended with another of less importance, but which equally served to inspire the Hollanders. The duke of Alva's grand fleet, equipped with great labour and expence, was defeated by the Zealanders. Though the action did not prove decisive, it greatly chagrined the duke, as Bossu, one of his best officers, was taken prisoner, and his fleet afterwards dreaded to look the enemy in the face. The year, and the government of Alva, concluded with a meeting of the states of those provinces subject to Spain. Here they deliberated on the means of continuing the war; read, and disregarded a remonstrance

sea.

United
Provinces

sent by the prince of Orange, complaining of the violence of the duke, demanding the free exercise of their religion for his party, restitution of the rights and privileges of the provinces, and that the foreign troops should be withdrawn. On the 2d of December, the Duke of Alva quitted the Low Countries, with his son Frederic of Toledo; and Don Lewis de Requesnes, appointed to succeed him, began his government with pulling down the insulting statue of his predecessor, erected at Antwerp; a popular act, that would have produced happy consequences, had not the court of Spain been infatuated with notions of despotism and blind superstition.

40
Duke of
Alva re-
signs.

Notwithstanding this success, the affairs of the States were yet in a most precarious situation; and their ability to support themselves appeared in the highest degree problematical. The new governor Requesnes had orders to push the war with vigour, and his antagonists prepared for the most obstinate resistance. The first advantages appeared on the side of the prince of Orange, by the surrender of Middleburg. But this was soon balanced by the defeat and death of prince Lewis of Nassau. The Spaniards, however, were prevented from pursuing the advantage they had gained, by a mutiny among their troops. This mutiny took place on a regular and well-concerted plan. The soldiers deposed all their officers, appointed new ones, and established a sort of community, vesting one of their number with the chief authority. The distresses of the Spaniards on account of this tumult were likewise augmented by a victory gained by the Zealanders at sea; when 40 of the Spanish ships were almost all taken or destroyed. Philip then perceiving that numberless difficulties would attend the reduction of the provinces by force, published an act of grace; but in such a limited manner, that it was unanimously rejected. Requesnes then determining to close the campaign with some remarkable exploit, laid siege to Leyden. The city was reduced to the utmost distress for want of provisions; the whole country was laid under water; and they could receive no relief except what was obtained by boats forcing themselves through the enemy to the city. In short, they were reduced to the brink of destruction, when a violent south-west wind drove the inundation against the works of the besiegers with such violence, that they were obliged to relinquish the enterprise for fear of being entirely swallowed up. In their retreat they were attacked by the garrison, and 500 of them destroyed. This disappointment for provoked the Spanish soldiery, that they deposed Valdes the commander whom they had chosen for themselves, and proclaimed their old one: a second mutiny ensued, and they marched in a tumultuous manner to Utrecht. Here, however, they met with a very unfavourable reception. Barlaumont the governor declared them rebels and traitors to their king; and gave free liberty to every one to massacre them wherever they could be found. The mutineers attempted to set fire to the gates; but being repulsed, and their leader slain, they capitulated, were received into favour, and sent into winter quarters.

41
Mutiny in
the Spanish
army.

The year 1575 commenced with some negotiations for peace; but these proving ineffectual, though the emperor interposed his mediation as far as possible, the war was renewed with redoubled fury. Fortune now

declared in favour of the Spaniards; and the States were reduced to such despair, that they began seriously to think of making an offer of the provinces to some Protestant power who might be able to defend them against the tyranny of the Spaniards. This offer was made to queen Elizabeth of England; but she declined it, for political reasons. A negotiation was even set on foot for this purpose with France, in favour of the duke of Anjou; but it ended in nothing besides the advantage of establishing a mart at Calais for the disposal of the prizes made by the Gueux. Philip, however, notwithstanding his power, had the utmost difficulty in supporting the expence of the war. He had already borrowed more than 40,000,000 crowns from the Spanish and Genoese merchants, and the interest still unpaid now amounted to as much as the capital. The war had besides cost a greater sum sent in specie from Spain and the Indies, which, with the immense losses occasioned by the stagnation of trade in the Netherlands, had quite exhausted the treasury. Large arrears were due to the troops; they were every day mutinying, and some broke out into actual rebellion. To remedy these evils, Requesnes demanded a supply of the provinces; and they answered him, by requiring restitution of their privileges, and dismissal of the Spanish troops. Flanders, in particular, paid the desired subsidy, by balancing it against half the damages the province sustained from the misconduct of the governors, and the wars wantonly and unnecessarily excited. While this affair was in agitation, Requesnes died of an ardent fever; and the council of state assumed the administration, and the prince of Orange took the opportunity of the confusion that ensued to lay the first foundation of the Pacification of Ghent, by which his affairs were considerably retrieved, and the greatest blow given to the court of Spain he had yet sustained. All now was anarchy in the Low Countries. The garrison of Ziriczee mutinied for want of pay; and to appease them, the council of state sent 100,000 livres, which the Walloon regiments under Madragon seized upon, after expelling the Spanish soldiers, wounding and murdering their officers. This did not unite the Spanish mutineers among themselves: they turned out the few remaining officers, and made new appointments. Joining with the garrison of Lillo, they marched, to the number of 2000 men, towards the capital; committed horrible outrages; overwhelmed the inhabitants of Brussels with conflagration; and, upon the 26th of July, seized upon Alost, confined the principal burghers, and hanged up a king's officer. The most favourable conditions were offered by the council of state, in order to appease the tumult, and provisions were sent to the mutineers. This created suspicion in the inhabitants of Brussels, that the mutiny was excited by the connivance of the council, with a view of ruining the provinces, without incurring the resentment and odium consequent on any appearance of legal oppression. They arrested the council, declared the Spaniards rebels, and took measures in concert with the other cities and provinces for expelling foreigners out of the Netherlands. A confederacy to this purpose was formed between the provinces of Hainault, Artois, and Flanders, to which all the rest except Luxembourg acceded; and Don John of Austria, who had entered the Low Countries in quality of governor and successor to Requesnes, was obli-

obliged to live in obscurity in Luxemburg, until the storm should subside.

The prince of Orange was all this while profiting by these commotions. He had long laboured to have the States-General convoked; and he now saw them not only assembled, but preparing to make head against the Spaniards, by a strange vicissitude of fortune, arising from accidents which all his penetration and sagacity could not foresee. United in councils against the common enemy, every measure was taken for reducing the citadels of Ghent, Antwerp, and Maelricht, the chief places in the hands of the Spaniards, and what must principally contribute to their expulsion. Ghent citadel was taken on the 27th of November, by the assistance of a strong reinforcement of troops and artillery sent by the prince of Orange. At Antwerp the states of Brabant were less successful. The citadel was vigorously attacked; but the mutineers at Alost entering the citadel to assist their countrymen, a sally was made, the besiegers were driven from their trenches, great part of the town was consumed by fire, and the rest pillaged for three days with every kind of insolence and brutality, at a time when Antwerp was the most flourishing and populous city in the Netherlands, and indeed among the most wealthy in Europe. It is affirmed that the treasure carried off amounted to four millions, besides an infinity of rich merchandise. This terrible calamity united Papists and Protestants without distinction in a confederacy, and co-operated with the measures of the prince of Orange to form the Pacification of Ghent: which was a confederacy of all the provinces to expel foreign soldiers; to restore the ancient form of government; to refer matters of religion to the several states of the provinces; for ever to unite the other 15 provinces in the same common interest with Holland, Zealand, and the prince of Orange; to renew the commerce and amity between them; to assemble the states in the manner practised under the house of Burgundy and Charles V.; to suspend all the rigorous edicts of the duke of Alva on the subject of religion, until the States-General should take the matter into consideration; to release all the natives made prisoners, mutually, without ransom; and to restore all things upon the same footing as before the war, and the tyrannical government of the duke of Alva.

The States-General began with soliciting aid from the queen of England. Their ambassador had a gracious reception; and Elizabeth advanced them 20,000*l*. sterling, on condition that the French should not be invited into the Netherlands, that they would accept of reasonable terms of accommodation if offered, and that the loan should be repaid the ensuing year. Next a cessation of hostilities was agreed upon with Don John, upon his assurances that every reasonable request of the provinces should be granted. On the 27th of December, deputies were sent with proposals to Don John to disband the foreign troops; but he desired to know what security the states would give for their allegiance after the departure of the Spanish forces; and remonstrated against the unreasonableness of disarming the king, while his rebellious subjects were in arms, and ready to seize the first opportunity of deserting their obedience. He likewise demanded security with respect to religion; and insisted so warmly on this head, that it was obvious he had no inclination to part with

the Spanish army before the provinces of Zealand and Holland embraced the Catholic religion. After much altercation, necessity at length obliged Don John to grant all that was required, to confirm the Pacification of Ghent, and dismiss the Spanish army. He had the king's authority for his proceedings; the treaty was proclaimed at Brussels and Antwerp on the 17th of February; and Don John immediately acknowledged governor, and the king's lieutenant of the Netherlands.

It must be observed, however, that when this edict was signed, the provinces of Holland and Zealand, by the advice of the prince of Orange, made the following objections, viz. that the States-General had not established the right of assembling this sovereign tribunal in the persons originally invested with that power by the constitution; that in some particular instances they had suffered an infringement of their privileges; that the Spanish troops were allowed to carry off the immense wealth they had acquired in the Netherlands, and by the destruction of the city of Antwerp in particular; that no stipulation was made in favour of those dispossessed of their estates, &c. For these reasons the States and the prince refused to sign the edict, though they consented to all the articles that did not contradict those specified. This raised a contention, by which the public peace was soon broken. Don John was strenuous in recommending violent measures against the prince and his party. To this purpose he wrote a letter in cypher to the king; but this letter fell into the hands of Henry IV. of France, who transmitted it to the prince of Orange. Escovedo, secretary to Don John, was next sent into Spain with a message to the same purpose; but the governor becoming impatient for his return, left the country himself, under pretence of complimenting Margaret queen of Navarre on her journey to Spaw. In this expedition he seized on the citadel of Namur; but attempted to justify his conduct to the States, by representing, that he was under a necessity of retiring to a place of safety, while he saw the flames of war and rebellion ready to break out all around him; and concluded with desiring the States to disarm the burghers of Brussels, who were closely attached to the prince of Orange. This letter was answered by an invitation from the States to return; promising at the same time, that they would to the utmost of their power bring to punishment all those who should form any designs against him. This, however, was not only refused, but the whole tenor of his conduct afterwards shewed, that he was resolved to commence hostilities, and that he was encouraged to do so by Philip. The event Don John was, that Don John was deposed from his dignity, the archduke Matthias was appointed governor-general, and preparations were made for a new and vigorous war. The Spanish troops were ordered to assemble in Naples and Milan; levies were made in Burgundy and Luxemburg; and a resolution was taken of supporting Don John with the whole power of the Spanish monarchy. To oppose this formidable power, the States, in 1578, entered into a new treaty with the queen of England; by which that princess agreed to advance them 100,000*l*. Sterling, and to assist the provinces with 5000 foot and 1000 horse; on condition that the loan should be repaid with interest in

eight months; that certain towns should be ceded to her in security; and that the States should defray the expence of transporting their troops, and take them in to pay, while they acted in their service. Elizabeth, however, afterwards departed from these conditions, under pretence that the French would suspect her having some designs on the Netherlands, and would for that reason unite their forces with those of Spain against her. Instead of the English troops, she now proposed to send John Casimir, count Palatine, with 3000 foot and 3000 horse; refusing at the same time to pay the money stipulated, until the States had consented to this alteration.

53
Amsterdam
concludes a
treaty with
the prince
of Orange.

Before this treaty was concluded, Don John was joined by an army of 16,000 foot and 2000 horse, all chosen veterans, commanded by Alexander Parnese, duke of Parma, the best officer in the Spanish service. Being thus superior to the prince of Orange, the Spaniards gained several advantages; which, however, were more than balanced by the loss of the city of Amsterdam. This place had been closely blocked up for several months by sea and land, and at last concluded a treaty with the friends of the prince of Orange, by which it was stipulated, that the Protestants should hold their religious meetings without the walls, and have a burying place within; that the garrison should be disbanded, and 600 men, commanded by the burghers, levied for the defence of the city; that all persons banished on account of religion should be recalled; that Amsterdam should enjoy all its ancient privileges, and that all vacancies in public employments should be filled without distinction of party or connection. This capitulation, however, was soon after broken; the Catholic magistrates were driven out of the city, attended by the priests and Popish clergy of every denomination; the images were pulled down, and only the reformed clergy suffered to preach publicly. Some ineffectual negotiations next took place; after which the States, sensible that the misfortunes and losses in the winter arose from the irresolution of the provincial states, vested the archduke, the council of state, and the prince of Orange, with a power of levying what number of troops they should think necessary, and disposing of them as they thought proper, without referring to the states in every particular: they only recommended that they would proportion the expences to the revenue, which at that time amounted to 600,000 l. vres. About this time a revolution, greatly beneficial to the common cause, was effected in Guelderland; John of Nassau, brother to the prince of Orange, had been appointed governor of this province. Upon entering on the administration, he perceived that the whole conduct of affairs was in the hands of persons strongly affected to king Philip and the Catholic religion; most of the cities professed Popery; and the count, who had sworn to the pacification of Ghent, was restrained from attempting any change in religion. The face of affairs, however, took a sudden turn; John acquired great popularity, and soon discovered that foreigners were the leading persons. By his artifice and policy he stimulated the people against them; they were deprived of their seats in the provincial states, and turned out of their offices in the government of the cities. Thus Nassau obtained the chief direction, and was able to co-operate with the

54
Revolution
in Guelder-
land.

measures planned by his brother. Another revolution happened in Groningen, of which the sieur de Billy was governor. Billy was by birth a Portuguese, by religion a Catholic, and consequently a dependent on the court of Spain: he refused to accede to the union of the provinces, and the States-general found it necessary to send to him Francis Martin Stella, with proposals for signing the pacification of Ghent. Billy suspecting that the deputy's real design was to excite a revolt in the province, put him to the torture to extort confession; after having first wounded him with his own hand. The deputy bore the most excruciating tortures with firmness; and having a surgeon to dress his wound to enable him to undergo a second trial, he communicated something in the Greek language, which the surgeon soon made public: in consequence, the mob assembled, rescued Stella, declared for the pacification of Ghent, and obliged Billy to quit his government. The change of councils in these two provinces was of the utmost service to the confederacy; and would have enabled the province to have encountered the whole power of Spain, had not their affairs been distracted by dissensions among themselves.

At last the prince of Orange, perceiving that little confidence was to be placed in the unanimity of provinces rent by faction, different in religion, and divided by ambition, political maxims, and private interest, formed the scheme of more closely uniting the provinces of which he was governor, and cementing them with those more contiguous, in which the Protestant interest prevailed. Such an alliance was subject to fewer difficulties than attended the more general one of uniting all the provinces; it was in fact the only measure that could be proposed with safety, and it was prosecuted with that alacrity and address for which William was deservedly celebrated.

On the 23d of January 1579, deputies from the provinces of Holland, Zealand, Utrecht, Friesland, Groningen, Overijssel, and Guelderland, met at Utrecht, and signed the alliance ever since known by the name of the *Union of Utrecht*, the basis of that commonwealth so renowned by the appellation of the *United Provinces*. This treaty of alliance was founded upon the infraction of the pacification of Ghent solemnly acceded to by Philip, and the late invasion of certain towns in Guelderland. It was not hereby intended to divide the seven provinces from the other ten, or to renounce the pacification of Ghent; its object was to preserve the liberty stipulated in that pacification, by more vigorous operations, and united councils. The chief articles of this union are the following.

55
Union of
Utrecht.

The seven provinces shall unite themselves in interest as one province, never to be separated or divided by testament, donation, exchange, sale, or agreement; reserving to each particular province and city all its privileges, rights, customs, and statutes. In all disputes arising between either of the provinces, the rest shall interpose only as mediators. They shall assist each other with life and fortune against every foreign attempt upon any particular province, whether to establish sovereignty, the Catholic religion, arbitrary measures, or whatever else may appear inconsistent with the liberties of the provinces and the intention of the alliance. All frontier towns belonging to the United Provinces, shall, if old, be fortified at the expence of the

United
Provinces.
55
And in
Groninge

United
Provinces.

the provinces; if new, at the joint expence of the union. The public imposts and duties shall be farmed for three months to the highest bidder, and employed with the king's taxes in the public service. No province, city, or member of the union, shall contract an alliance with any foreign prince or power, without the concurrence of all the other members. Foreign powers shall be admitted into the alliance, only by consent of all the contracting parties. As to religion, the provinces of Holland and Zealand shall act in that particular as they think advisable; the rest shall adhere to the purport of the edict published by the archduke Matthias, which prescribed that no man should be oppressed on the account of conscience. All the inhabitants, from the age of 18 to 60, shall be trained and disciplined to war. Peace and war shall be declared by the unanimous voice of all the provinces, other matters that concern the internal policy shall be regulated by a majority. The states shall be held in the usual constitutional manner, and coinage shall be deferred to future determination. Finally, the parties agree, that the interpretation of these articles shall remain in the States-general; but in case of their failing to decide, in the lastholder.

This alliance was so universally approved, that in a short time the cities of Ghent, Nimeguen, Arnhem, Leewarden, Venlo, Ypres, Antwerp, Breda, Bruges, with several other towns, besides a great number of noblemen and persons of distinction, embraced and signed the union. Thus the foundation of a commonwealth was laid, but in a fluctuating and uncertain state of affairs, when men were actuated by different passions, views, and interests; intimidated by the great strength of the Spanish monarchy, and supported chiefly by a zealous adherence to liberty, and firm resolution to perish in defence of freedom. The first coin struck after this alliance is expressive of the situation of the infant republic. Here was represented a ship labouring amidst the waves, unassisted by sails or oars, with this motto, *Incertum quo fata ferant*.

It was expected, that the important object of this alliance would have attracted the attention of the Walloons, and indeed of all the Catholic inhabitants of the Netherlands: it in fact did so, but in a different manner from what was imagined. The Walloons not only refused to accede to the union, but they made the strongest remonstrances to the States general upon the danger, impropriety, and illegality of such a confederacy. It appears from Strada and Bentivoglio, that the duke of Parma was at the bottom of their intrigues. He stimulated and prompted their measures, inspiring them with a jealousy of the Protestant designs on the Catholic religion. In the end, he contracted an alliance with them; and thereby confirmed by his own example the legality and necessity of the union of Utrecht. Immediately they began levying an army; but still kept up appearances with the confederated provinces, though it was obvious that hostilities must soon commence. To prevent the effusion of blood, the emperor, as mediator, set on foot another negotiation; but Philip would allow no reasonable terms of accommodation, and give no security for liberty of religion. Instead of granting equitable conditions, he laboured to detach the prince of Orange from the union; made him extraordinary proposals; offered to restore him to

all his estates, indemnify his losses, raise him to the height of power, and give him the first place in his esteem and favour. But William was too wise to rely on the promises of a king, who had shown himself perfidious. He determined to share the fate of the United Provinces, to fulfil his engagements, and the hope conceived of his conduct.

In the mean time great disorders arose in Ghent. The inhabitants, finding that the Walloons refused all proposals of agreement, began afresh their violences against the Catholics. Their example was followed by Oudenarde and Dendermonde; and to such excess did they push their zeal, that the presence of the prince of Orange was necessary to restore the tranquillity of Ghent in particular. On the prince's arrival, he found every thing in confusion; the convents and churches pillaged by the soldiers, the houses and effects of the Catholic priests fold at public markets. But he soon put a stop to those arbitrary and iniquitous proceedings, and the Catholics were restored to the full possession of their estates: an instance of justice which, however, could not procure William the confidence of the Catholic faction; who esteemed the man, while they detested the heretic. An attempt was made by the Walloons to surprize the city; but it was frustrated by the prince's vigilance and prudence.

While the prince of Orange was busied in conciliating factions, forming alliances, and strengthening the union, the duke of Parma was taking measures to disconcert his projects, and reduce the provinces to the king's obedience. He dispatched Gonzaga and Mondragon with 8000 men to lay siege to Mursien. The town was taken by assault; the governor hanged; and 45 of the chief inhabitants were tortured to death, for having valiantly defended themselves, and faithfully discharged their duty. It is said the duke of Parma disavowed this bloody proceeding, so inconsistent with the character of a hero. After some farther considerable advantages obtained in the neighbourhood of Ruremonde, the king's army insulted Antwerp, where the archduke and the prince of Orange then resided. The states army was intrenched near Borgerhont, a post attacked without success by the duke of Parma, after a brisk skirmishing of two hours between the armies. La Nove, however, the general of the states army, not choosing to expose himself to continual alarms from the enemy's cavalry, retired under the cannon of Antwerp.

On La Nove's retreat, the duke of Parma invested Maelricht. The siege began on the 8th of March, and continued without remission to the 29th of June. This defence was deemed very extraordinary, as the fortifications were in bad order, the garrison slender, and the place but poorly provided with the necessaries of a siege. One Sebastian Tappin, an engineer by profession, a Protestant, and a brave and alert soldier, by his indefatigable vigilance raised continual obstructions to the duke's approaches. The garrison had sustained frequent assaults, and made divers bloody sallies, by which they were so much fatigued, that during a parley the town was surprized, and a great many soldiers were put to the sword; but Tappin was saved by favour of the duke of Parma, who gave strict orders that he should have quarter. For three days Maelricht was a scene of the utmost desolation and horror, the Span-

nish soldiers committing every excess and enormity, in despite of all the endeavors of the general to restrain their licentiousness, and maintain discipline. With such diligence did the duke apply himself to this siege, that unable to support the fatigue, he was seized with a fever, which had near proved fatal. His situation inspired the enemy with fresh courage. They ventured to appear in the field; reduced Alolt, and some other places of little consequence; but could not prevent the loss of Menin taken by assault, though it was soon after retaken by the prince of Orange. In Brabant the states likewise obtained some advantages, though of too unimportant a nature to merit attention. The truth is, all the United Provinces were in a deplorable situation; and their trifling successes were owing entirely to accident, or the duke of Parma's illness. Several provinces contributed nothing to the common cause; others furnished but a small proportion of the taxes agreed upon at the union. The army had large arrears due, and lived at discretion; in a manner more oppressive to the people than taxes to the amount of their regular pay. The people clamoured against the states; they threw the blame on the officers for relaxing in the point of discipline; and the officers recriminated, alleging, that the fault was in the states, who failed in performing their engagements to the army. All was in confusion; but as no person would acknowledge his error, there appeared little hopes of amendment. In a word, nothing besides the same distress in the Spanish army could have prevented the duke of Parma from reducing the revolted provinces to accept any terms he should think fit to prescribe. He was equally in want of money; and his late treaty with the Walloons required that he should dismiss all his foreign troops in the space of six weeks after the publication of the treaty. His situation indeed was so deplorable, that he requested leave to resign his command, and retire with the foreign soldiers to Italy; but the court of Spain had too much confidence in his ability to entrust so important a charge to another. In this state of affairs the animosity of the parties remained, without the power of showing their resentment. The states were resolute, but unable to defend their liberties. Philip was determined, but too weak to be despotic; and both were obliged to content themselves with publishing bitter remonstrances against each other.

At last the prince of Orange renewed the treaty with the duke of Anjou. The queen of England was again offered the sovereignty, but she declined it for political reasons. The duke of Anjou was, however, opposed by a great number of the Reformed, on account of the share his mother had in the horrid massacre of the Protestants at Paris. All arguments to remove their prejudices were in vain. Anjou was a Roman Catholic, and that alone was sufficient to render him detestable. The prince of Orange urged the necessity of receiving the prince. Theologians and civilians allowed that it was lawful to have recourse in extremity to a Papist, but the people continued obstinate. This determined the prince of Orange to have recourse to the States-general, to whom he sent a long remonstrance, pointing out the causes why the confederacy did not produce the intended effect; and exhorting them to re-consider the affair respecting the duke of Anjou. In consequence, the States-general refer-

red the prince's remonstrances to the provincial states and cities; and after long deliberations, and warm debates, it was at length determined, in 1380, to call in the duke of Anjou, as the only resource in so great a calamity. Accordingly the year began with a solemn treaty, whereby the United Provinces renounced their allegiance to Philip, and acknowledged Francis Hercules de Valois, duke of Alençon and Anjou, for their sovereign. The treaty consisted of 27 articles, of which this we have mentioned was the chief. Deputies were sent to the duke of Anjou, to explain the articles, and congratulate him on his accession. As to the archduke Mathias, finding himself unsupported by the emperor, the empire, and the numerous fiends whom he expected would have joined him on his elevation, he expressed no repentment at the conduct of the provinces, which with great moderation he attributed to necessity. He only demanded to know their intention with respect to his own person; and the states made their apology, by representing the situation of their affairs, assuring him of their esteem, permitting him to reside in the Netherlands as long as he thought convenient, and highly applauding the prudence and equity of his conduct during his administration. As to the provinces of Holland and Zealand, they were left wholly in the hands of the prince of Orange, whose power as stadtholder was in no respect limited by the duke's sovereignty. After all, Grotius affirms, that the duke's authority was merely nominal, that the real power devolved on the prince of Orange, whose name, however, was used in all public acts only in a subaltern capacity. It was apparent indeed to the French, that William concealed ambitious views under the cloak of patriotism; but it was not convenient to discover their sentiments.

When the king of Spain was informed of this open defection of the Provinces, he attributed the whole to the prince of Orange, and proceeded directly to proscribe him; he confiscated his estate, upbraided him with ingratitude, and stained his character with ignominy. He even promised a reward of 25,000 crowns to whoever should bring him the prince of Orange dead or alive; the same to his heirs, in case the person perished in the enterprise; and he declared all those proscribed, their estates confiscated, their honours and dignities abolished, who adhered to William a month after the publication of this edict.

The prince of Orange did not silently pass over this proscription. He employed one Villiers, a Frenchman, to refute the edict: his answer was well received, and is recorded by historians as a proof of the spirit, the equity, the prudence, and the moderation of the prince. However, when it was proposed to the states for their opinion, with a request they would publish it in their own name, they declined it; assigning for a reason, that it contained some facts too little known to be credited, and perhaps too much acrimony and resentment against a prince whose power they still dreaded. With these recriminations ended the transactions of the year.

The following year the states, after long deliberations at the Hague, published an edict, excluding king Philip from any sovereignty, right, or authority over the Netherlands. This writing appeared on the 26th of July, 1581, under the title of *The Abdication of Philip king of Spain*. It was extremely well drawn up; it

stated in the strongest manner the mutual privileges of the king and people; proved that the allegiance of the latter was voided by the breach of contract on the side of the former; enumerated the oppressive and tyrannical acts of his government; set aside his authority for the most cogent reasons; forbid money to be coined in his name; and took every other step towards independence. It was in vain for Philip to remonstrate: he knew the states were to be convinced only by the sword; to this therefore he appealed. The duke of Parma blocked up Cambray so closely, that the garrison was reduced to the extremity of living upon horses, dogs, and cats; though they still refused to capitulate, in hopes of being succoured. At length the duke of Anjou assembled a body of 10,000 foot and 4000 horse, and approached Cambray. The viscount de Turenne and count Voulondou, undertook to force themselves with a body of men into the town, but they were surrounded and taken prisoners by the Spaniards. This disappointment did not discourage the duke of Anjou: he still pressed forward with intention to attack the the Spanish lines; but the duke of Parma, not caring to hazard a battle, deserted his works, and retired to Bouchain. As soon as the duke of Anjou entered the city, he took an oath to govern it agreeable to its ancient laws, and to preserve the citizens in the full possession of all its liberties. He was now pressed by the states and the prince of Orange to march directly into Flanders: he endeavoured to comply; but his army, composed chiefly of volunteers, was so weakened by desertion, that the design was laid aside.

It was about this time that the duke of Anjou resumed the notion of addressing Elizabeth queen of England. Not deterred by the ill success of his former negotiation, he determined upon a voyage to England; an excursion which proved equally unsuccessful to himself and unfortunate to the United Provinces, as during his absence the duke of Parma made himself master of Tournay, which concluded the transactions of this campaign. He was magnificently entertained, led into a persuasion that all would succeed according to his wish, and at length tired out with tedious expectation. In his absence, St Guilan was reduced by the prince of Espinoy. This general directed his march towards Dunkirk, with intention to join the French forces. The duke of Parma, who had notice of his motion, repaired to seize the opportunity of investing Tournay. He began his approaches, and was vigorously received by that garrison, inspired by the courage of the princess Maria d'Espinoy, niece of the count Horn so cruelly beheaded by the duke d'Alva. The town was stormed in breach by the duke of Parma, who supported the assailants in person, received a wound, and had the mortification to see his Spaniards thrown headlong from the walls. The duke of Anjou repeatedly promised succours; but either forgot, or could not perform his engagements: the latter indeed is the most probable; as he was certainly a dupe to the superior policy of Elizabeth, who had not yet declared openly in favour of the states. In the end, despairing of relief, harassed with perpetual watching, and weakened by losses, the garrison capitulated on the 29th of November. The conditions were honourable; and the princess d'Espinoy was treated with particular marks of distinction by the duke of Parma, who

highly esteemed the heroic qualities of this amazon. This advantage was succeeded by another, obtained by the Spanish general Verdugo, over the confederate army in Friesland, commanded by general Norris and William Lewis of Nassau, a young prince of great expectation. It appears from the Spanish account, that Norris was attacked in a defile, where he could not draw out his troops in battalia; and that he was put in confusion, and defeated with great loss. On the other hand, the Dutch writers allege, that he attacked the enemy; but being inferior to them in cavalry, retreated in good order, with scarce any loss.

The year 1582 began with a spectacle very unusual in the Netherlands, the public entry of a sovereign elected by the people. The duke of Anjou setting sail from England on the 8th day of February, arrived on the 10th at Flushing, where he was received by the princes of Orange and d'Espinoy. Next day they set out for Antwerp with a magnificent retinue, and went up the Scheldt attended by 50 barges. His reception at Antwerp was splendid beyond any thing ever seen in the provinces; they even exceeded the preparations made for Philip himself on his being appointed to the government in the Netherlands by Charles V. his father. A theatre was erected before the walls of the citadel, in which was placed a chair of state, covered with cloth of gold. There the duke was seated, and the conditions were read to him, upon which he was received as duke of Brabant. When he had sworn to observe the articles, he was clothed with the ducal robe, and his head adorned with the ducal coronet by the prince of Orange; who said, "I will pin it in such a manner that it will not be easily shaken;" an expression which at that time was taken for a happy omen, though it soon proved fallacious.

While the states of Brabant were employed in festivity and mirth, a Biscayan merchant, named *Gasper Anasra*, had contrived a project to redeem his shattered fortune by the death of the prince of Orange. He corrupted one of his domestics, by the promise of half the reward, to strike the blow. The assassin entered the citadel; and as the prince was passing after dinner into another room, discharged a pistol, and dangerously wounded him behind the ear. The prince was stunned with the force of the ball, and before he recovered the assassin was killed by his attendants; which prevented for a time the absolute discovery of the plot, though it afterwards appeared from circumstances. It was traced that he had confessed the secret to a Dominican named *Antonio Tunnmermon*, receiving from the wicked priest absolution, and a promise of eternal reward. Tunnmermon was hanged, drawn, and quartered, his limbs being fixed upon the walls of Antwerp. But though for this time the prince escaped the danger, he was in 1584 assassinated at Delft, by one Bal-
thazar Gerrard or Guion, a person who had before served his highness with fidelity and zeal. He was at that very time employed by the prince to carry letters into France, and had received money to bear his expenses, with which he purchased pistols to murder his benefactor. At the criminal's examination, it appeared that he had long meditated this bloody action, and was confirmed in his resolution by the Jesuits and Catholic priests; he even affirmed on the rack, that the duke of Parma was privy to the design, who promised

he should have the reward : upon the whole, Gerrard seems to have been an enthusiast, and his crime the result rather of insanity, than of any concerted scheme, or malicious intention. His punishment, however, regarded only the action : it was cruel beyond measure, shocking to humanity, and a striking instance of the vehement party-spirit of the times; not of the justice of the judges, or the attachment of the people to the prince of Orange.

The United Provinces were now in a most deplorable situation. The duke of Anjou had been totally unable to resist the duke of Parma, in consequence of which many towns had been taken; and in other respects the states had sustained immense losses. The duke of Anjou, chagrined and disappointed, had retired to France, where he died. But above all, the loss of the prince of Orange seemed to give the finishing stroke to the affairs of the states; and confusion and anarchy now reigned in their councils. The provinces of Zealand and Holland alone endeavoured to repair the loss, and show their gratitude to William by electing his son Maurice their stadtholder and captain-general by sea and land. Maurice was at that time only 18 years of age; but appeared in every respect worthy of the high dignity which had been conferred upon him. The first step taken by the confederates was a solemn renewal of the treaty of Utrecht; after which the most vigorous preparations were made for the defence of the country. But before any thing of consequence could be done, the duke of Parma had reduced Lilloenhouk, Dendermonde, Vilvorde, Ghent, and Antwerp; which struck the states with such terror, that they again offered the sovereignty to queen Elizabeth. This was once more refused; though that princess engaged, by a new treaty, to assist the States both with men and money. An army was accordingly sent into the Netherlands under the command of the earl of Leicester; but it does not appear that this was of any essential service to the cause; for the conduct of that general was so exceedingly improper, that he was not only baffled in every military enterprise, but drew upon himself a general odium. It is very probable indeed that the States could not long have supported themselves in such circumstances, had not Philip rashly engaged in a war with England, with whose naval power he could scarce be enabled to cope by any superiority in numbers whatever. The defeat of the Spanish armada in 1588, gave such a blow to the power of that nation, as totally disabled them from carrying on the war in the Netherlands. Instead of sending the proper assistance to the duke of Parma, that general received orders to hasten to the aid of the duke of Mayence, who had been defeated by Henry IV. The duke was obliged to comply with this order, though he was sensible the loss of the United Provinces must be the consequence. Prince Maurice now carried every thing before him; and by the end of the year 1591, the Dutch saw their frontiers extended, the whole country secured by rivers and covered by fortified towns, with the greatest probability of driving the Spaniards out of Friesland in another campaign.

The remainder of the history of this war is only a detail of the Spanish losses and misfortunes, which now ensued. Their affairs were at last totally ruined by a

decisive victory gained by prince Maurice, in the year 1600, over the archduke Albert, who had been appointed the Spanish governor of the Netherlands. King Philip II. died in 1598, leaving the affairs of his kingdom in the most distressed situation; notwithstanding which, his successor Philip III. was too haughty to consent to peace, or allow that the States were free, though he was plainly unable to keep them in subjection. At last, in 1606, the courts of Madrid and Brussels began to think of peace in good earnest. In 1607 a suspension of hostilities took place, and in 1609 a treaty was concluded. In the first article of the treaty, the archduke, in his own and the king of Spain's name, acknowledged the United Provinces, and renounced all claim to sovereignty over them, but in such general terms as would admit of altercation. In the second, a truce for 12 years, by sea and land, through all the dominions of both parties, was concluded. By the third article, the parties were to remain in possession of what they now held, without cession or exchange. In the fourth, a general amnesty was stipulated, and full freedom of trade by sea and land to each others dominions granted. This necessarily implied a cessation of hostilities in the Indies; however, great debates afterwards arose upon this account. Spain observing the rapid progress of the Hollanders in the India trade, apprehended they would soon become too powerful in that quarter; and the Dutch were willing to maintain the advantage of their superiority. Both, for this reason, disputed the article; yet it could not be set aside without destroying the whole treaty, and the fruits of all their laboured conferences. The fifth article regulated the imports, and the duties to be paid by the subjects of the archduke and the States, trading to each others dominions, which were to be on the same footing with those of other nations. The archduke used his utmost endeavours to have the duties at Lillo, on the Scheld, abolished, and the commerce of Antwerp restored to its former grandeur; but this was so diametrically opposite to the interest of the Hollanders, that it was impossible it should ever take place. The sixth and seventh articles likewise regarded commercial affairs. But it would be unnecessary to dwell on particulars. Sufficient is it, that the truce was mutually beneficial, Spain being no longer in condition to support the war, and the Hollanders having obtained the end of all their desperate resistance and invincible perseverance in the cause of liberty. Philip of Nassau, by the truce, entered into possession of all his paternal estates in the Spanish Netherlands and Burgundy; while the States rewarded the faithful services of Maurice with a pension of 25,000 florins, to be paid annually out of the public treasury, besides an appointment of 60,000 francs as governor-general. Pensions were likewise settled on the other princes of the house of Nassau: all were gratified in a manner that demonstrated the high sense the republic had of their merit, though they might possibly be disappointed in their great design of raising prince Maurice to the sovereign authority.

No sooner were the Dutch freed from this extreme danger, and felt the blessings of liberty, than dissensions among themselves took place. The disputes betwixt the Arminians and Calvinists produced violent disturbances, which frequently ended in the persecution of the former. In 1621 war was renewed with

Spain; and it may be remarked, that during the whole course of it, the subjects of the republic traded to the Spanish ports, as if there had been an entire friendship subsisting between the two nations. It was no uncommon practice with them to supply towns with provision that were besieged by their own armies; and to furnish the enemy with ammunition and other necessities, without which they could not carry on the war. Their motive and apology for this conduct was, that thus they kept in their own hands the profits by which other nations would be enriched. By steadily pursuing this line of conduct, making as many prizes as they could by force, and at the same time making as much profit of their enemies as could be obtained by a lucrative trade, it is no wonder that the republic should flourish, and rival in wealth the greatest nations of Europe. In 1628 the Spaniards met with a dreadful blow by the capture of their flota from Mexico. This was the greatest prize the Hollanders had ever met with; being valued at no less than 15,000,000 livres. From this time the Spaniards were every where defeated and baffled in almost every enterprise they undertook; nevertheless, they carried on the war, with an obstinacy hardly to be matched, for 20 years longer. At last, in 1648, a treaty was concluded, by which his Catholic Majesty renounced all right and sovereignty over the Lords the States-general of the United Provinces, who were henceforth declared a free and independent republic, and that both sides should remain in the unmolested possession of what they held severally at the signing of the treaty.

From this time to the year 1670 we meet with nothing very remarkable in the history of the United Provinces. By invariably pursuing the maxims of prudence, industry, and frugality, the republic had attained the highest pitch of grandeur. Amsterdam was become the emporium of Europe, and the richest city in the universe. Holland alone contained 3,000,000 of souls, and all the other provinces were proportionably populous. The States dispatched ministers and consuls to China, Siam, and Bengal, to the Great Mogul, the king of Persia, the khan of Tartary, the grand Signior, the czar of Muscovy, and the princes of Africa. They were considered as an important weight in the scale of Europe, and no treaty was concluded without their ambassadors. The triple alliance with England and Sweden, into which they had entered, gave Lewis suspicion that they proposed to set bounds to his ambition, and clip those bold pinions which had so swiftly conveyed his conquests over the Low Countries. Van Beuningen's insolence, in comparing himself to Joshua stopping the course of the sun, which was the French king's device, highly disgusted his Majesty; who was shocked at the presumption and pride of a republic just started out of obscurity, and gained, in the space of a century, from the ocean. But what was still more alarming to Lewis, was the probability that the Dutch would ruin the manufactures of France, and his new established commerce of the Indies. His jealousy discovered itself in divers instances; and the pensioner De Witt, who at that time had the leading of affairs, his brother, and his party, did all in their power to remove these prejudices; but the unhappy differences which then prevailed in the United Provinces frustrated all their endeavours.

United
Provinces.

Lewis now fought every opportunity of breaking with the Dutch; less perhaps from any dread of their power, or ability to injure him, than with a view to enlarge his dominions by the entire conquest of the Low Countries. He knew that the whole strength of the republic consisted in her marine; that her frontier was weak, her provinces divided, and the chief power in the hands of men inveterately set against the family of Orange, the ancient captains of the republic. His first attempt was to dissolve the triple alliance, and disengage from it Charles II. king of England. In this business the duchess of Orleans was employed: he went to England under pretence of visiting the king her brother; and her negotiation was successful. In the mean time Lewis possessed himself of Lorraine, under pretence that duke Charles was forming alliances in the empire against France.

Treaty between the kings of France and England.

The following year was spent in negotiations with the emperor, Spain, and Sweden, with the electors of Cologne and Brandenburg, with the bishop of Munster, and other spiritual and German princes. The design of Lewis was to prevent their acceding to the triple alliance; from which he had already weaned one power, the most considerable of the whole. The bishop of Munster beheld with uneasiness the growing power of the United Provinces: he pretended that they had made several attempts upon the counties of Stirum, Culemburg, Bentheim, and East Friesland; that they had seized on Ravenstein on the Meuse, and several other places belonging to his bishopric. In his own defence he concluded a treaty with France, and prevailed on the elector of Cologne to follow his example. By signing a treaty with these two princes, the king opened a way to Holland by the Meuse and the Rhine; he established by this means places of arms and magazines in a country distant from his own dominions, and secured a retreat in case his enterprize proved abortive. With respect to the emperor, every artifice was used to keep him neutral; and indeed his own inclinations co-operated but little in favour of the Dutch, whom he regarded as subjects revolted from the princes of his family, and in possession of several places belonging to the empire. In Sweden, Lewis's negotiations were equally successful; for here he prevailed so far with Charles XI. as to obtain a stipulation, that if the emperor, or any of the princes of the empire, joined their forces to the Dutch, a Swedish army should march into the very heart of Germany and join the French, in order to force those princes to observe the treaty of Westphalia.

Of all the Germanic body, the elector of Brandenburg alone interested himself for the safety of the States-general. The peace of Westphalia had prevented this enterprising prince from extending his dominions in Germany, and retaking Pomerania from the Swedes. He had long aspired at the stadtholdership of Holland; and though that office had been for six years suppressed, yet he flattered himself, that in case of a war he might obtain it, perpetuate it in his family, and in time reduce Holland by dint of force, intrigue, and stratagem. With this view, he rejected the proposals of several princes of the empire, and even those of France, endeavouring by every possible method to insinuate himself into the friendship and confidence of the States. In the end he concluded a treaty

75
Peace concluded.

76
Flourishing state of the republic.

77
Cause of the war with France

with them, whereby it was stipulated that he should assist the republic with 25,000 men. Beverning, the Dutch ambassador at Madrid, disconcerted all the schemes of France at that court, and engaged the queen of Spain to furnish money and troops for the defence of the United Provinces. Thus was the face of Europe wholly changed. France and England, who had contributed largely to the raising and aggrandizing the republic, were now incited to destroy her; while Spain, which for an age had been endeavouring to suppress her, was arming for her support. Pierre de Groot, the Dutch minister at the Hague, was employed to penetrate into Lewis's designs; he gave his constituents notice that he foresaw a terrible storm ready to fall upon them, which they might nevertheless break by seasonable submissions and proper acknowledgments. Upon this the States wrote to the king, endeavouring to appease his wrath; but finding him inexorable, they prepared for receiving him, and provided for the security of their provinces. But the long peace the republic had enjoyed destroyed her standing forces, and little confidence could be reposed in her new levied soldiers.

80
Hostilities
commenced

As soon as matters were ripe for execution, Lewis ordered an army of 100,000 men to file off towards the Rhine. Before the opening of the campaign, and previous to his declaration of war, he divided his army into four columns; commanding one in person, with the marshal Turenne under him. Another was led by the prince of Condé, assisted by the marshals Humieres and Bellefonds; the third was headed by Crecqui; and the fourth marched to Westphalia under the conduct of the duke of Luxemburgh, to join the bishop of Munster. As the marshals Crecqui, Bellefonds, and Humieres, refused to receive orders from Turenne, they were banished; but after six months exile, were recalled, at the instance of the whole body of marshals in France, upon their making proper submissions.

Such an army drawing towards their frontiers could not but terrify the Dutch, now torn with civil factions. The partisans of the Orange family were for abolishing the perpetual edict, and raising William III. to the dignity enjoyed by his predecessors; but the De Witt faction opposed him violently, though they could not prevent the young prince from being chosen captain-general and high admiral. Many persons hoped that William's new dignity would incline his uncle Char. II. to return to the triple alliance; but that hope was frustrated by the conduct of his Majesty; who, in conjunction with the most Christian king, declared war against the States-general on the 7th day of April. A month after, the elector of Cologne and bishop of Munster followed the example of the two kings. The Dutch put themselves in the best posture of defence that circumstances would admit. Maastricht was strongly garrisoned; the prince of Orange had assembled an army of 25,000 men, with which he advanced to the banks of the Issel, and the Dutch fleet cruised off the mouth of the Thames to prevent the junction of the naval forces of England and France, which amounted to 150 ships. All Europe watched the first motions of two powerful kings, seconded by the best generals of the age.

His most Christian Majesty joined his army at Charleroy. It was composed of 23 companies of *gens d'*

arms, life-guards, musqueteers, and light-horse, two regiments of the French and Swiss guards, 14 regiments of foreign infantry, and 60 regiments of light horse or dragoons, comprising in all an army of 110,000 fighting men, under the command of marshal Turenne as captain-general. Holland could only be attacked by the Rhine or the Meuse; and the generals and ministers differed by which of these inlets they were to make the first impressions. At last, after several deliberations, it was determined to make both attacks at the same time, in order the more to disconcert their councils. It is probable that Turenne always opposed the siege of Maastricht; for we find him immediately after the surrender of Maastricht strongly dissuading the king from that enterprize, in opposition to the sentiments of the prince of Condé. At last he prevailed; and it was resolved in council to advance towards the Rhine, and besiege at the same time the towns of Rhinberg, Vessel, Orsoi, and Burick. These places were all well fortified, and deemed the keys of Holland; however, the Dutch did not appear disturbed at their being invested, as they were only under the protection, and did not immediately belong to, the United Provinces. They were besides in hopes, that any attempts upon the territory of Cleves would hasten the preparations of the elector of Brandenburg, and even rouse the emperor unto a sense of the danger he was in from the vast designs of Lewis. Nothing could oppose armies so well appointed, led by generals so skilful and so experienced. The four towns surrendered within a few days of each other; and Rhinberg, that held out longest, opened its gates on the 7th of June. A few days after, the town and fort of Rhees, and the town of Emerick, surrendered; upon which the king resolved to pass the Rhine by a ford, over which the cavalry were to swim. This bold enterprize was projected and conducted by Condé; who, in the face of two regiments of foot, and several squadrons of horse, under general Wartz, intrenched on the opposite side, effected the passage, in the same order, and with as much regularity, as if he had marched his troops on dry land. The enemy made a stout resistance; but were driven from their post, after having killed the duke de Longueville on the spot, and wounded the prince of Condé, which disabled him for some time from attending the service, and obliged him to resign the command of his army to Turenne.

It is almost incredible with what rapidity towns and fortresses yielded to the fortune of his Majesty's arms. The reduction of Betau, the most fruitful country of the United Provinces, and the surrender of Tolhus fort, obliged the prince of Orange to abandon the Issel, lest he should be attacked in the rear, and to retire to the very heart of the country, as far as Rhemen, in the province of Utrecht. By this means the town of Arnheim, the forts of Knofsembourgh, Voorn, St André, and Shenck, this last the strongest in the Netherlands, (having cost the great Henry Frederic prince of Orange, a few months siege), with a variety of other forts and towns, surrendered as soon as summoned; and at last Nimeguen, a town strong from the nature of the works and fortifications, and garrisoned by 8000 fighting men, including the inhabitants, was invested. After the citizens had for eight days exhibited signal proofs of cou-

rage

87

the French

United
Provinces.

rage in defence of their liberties, they were forced to yield to the superior skill of Turenne.

In the mean time the bishop of Munster and elector of Cologne, having joined that body of troops under the command of the duke of Luxembourg, the united army entered the province of Overysel, and by dint of cruelty, and terror which the duke spread, reduced the towns as soon as he appeared before them. Animated by that implacable rage that constantly attends religious wars, the two prelates obliged the duke to exert a severity, by no means suited to his nature, against heretics and the rebellious subjects of the house of Austria. Next the king's forces penetrated into the province of Utrecht, where their conquests went on with the same rapidity, and put the capital of the province in the utmost danger. To retard its fate, the Dutch could imagine no other expedient than opening their sluices, and overflowing the country. The other towns followed the example of Utrecht; and Holland, Brabant, and Dutch Flanders, was one vast lake, the towns rising like islands in the midst of the waters. Farther to stem the torrent of Lewis's conquests, the people were persuaded the only barrier was to lodge the supreme power in the hands of the prince of Orange. They accordingly obliged the states of Holland and West-Friesland to unite the dignity of stadtholder to those of captain-general and high admiral, with which the prince was already invested. They likewise sent remonstrances so pathetic to the king of England, that Charles, moved with the situation of the republic, and jealous of the designs of Lewis, dispatched the duke of Buckingham and earl of Arlington into Holland, to quiet the fears of the Dutch, and insist upon the king's penetrating no farther into Holland. In case of Lewis's refusal, Charles declared he would break the alliance; as he perceived, that, instead of securing Zealand to the English, agreeable to the treaty, the designs of France were to unite the whole republic to their own monarchy. His most Christian majesty had in fact no great regard to the menaces of his ally: but as persisting obstinately to advance into a country which the inundation rendered impassable, might terminate in the ruin of all his schemes, he seemed, out of compliment to the king of England, to listen to terms of accommodation; which, after all his victories, could not fail of proving advantageous. In the space of three months he had conquered the provinces of Guelderland, Overysel, and Utrecht, taken about 50 towns and forts, and made 24,000 prisoners. Condé and Turenne advised his Majesty to send the prisoners to work upon the canal of Languedoc, and to leave all the places that were not essential to the preservation of his conquests; the minister Louvois was of a different opinion, and his sentiments determined the king. The prisoners were released for a trifling ransom, and the king's army totally reduced and exhausted by the continual drains made to garrison the conquered places.

83
Unsuccessful
negotiation

A negotiation was set on foot at Bostel, near Boisle due, whither the king, attended by the English ambassadors and the Dutch deputies, repaired: but the terms required of the republic were so hard, that they were rejected with disdain by the Dutch; who, animated by their stadtholder, resolved to wait a change of fortune in the midst of the waters. They used every expedient to rouse the princes of Germany in

their defence; and so successfully, that the elector of Brandenburg, the nearest and most interested prince, prepared to take the field. The undaunted courage, the vigilance, and public spirit of the prince of Orange, gained him the intire confidence and affection of the republic; and excited their resentment against the two brothers De Witts, his implacable enemies, whom they accused of receiving pensions from Lewis. The suggestion was false; but possibly their love of liberty, and jealousy of the house of Orange, had carried those two great politicians too far in their pacific measures and complaisance to the power of the French monarch. The pensionary was attacked in the street by the populace; but by his personal bravery broke through the crowd, and saved his life, though covered with wounds. Soon after the sedition broke out afresh, and the partisans of the house of Orange again stirred up the animosity of the republic against the De Witts. Several crimes were laid to the pensioner's charge, but he cleared himself. Suborned witnesses accused his brother of an attempt to poison the prince of Orange. Cornelius was imprisoned, and treated with great barbarity. While he was under the torture, he sung that ode of Horace, *Justum et tenacem propositi virum*. His brother took him out of prison after sentence of banishment was pronounced; the tumult rose high, and both the De Witts were cruelly torn in pieces in the streets. William of Orange seemed touched at this terrible sacrifice; he made the pensionary's eulogium, and ordered the murderers to be prosecuted; however, the clemency he showed them, the advantages he obtained by the massacre, and the animosity he bore the De Witts, convinced all men that he countenanced the murder.

William of Orange in the mean time daily ingratiated himself more. He gave up his whole fortune for the safety of the state; and exerted himself with such prudence and ability, that all Europe began to unite against the two kings by the month of July. Every prince in Germany was in motion to succour the Dutch. The emperor, the king of Denmark, the elector of Brandenburg, the duke of Brunfwik Lunenburg, the landgrave of Hesse, immediately ordered their troops to join; several of the other princes were preparing to take the field. All were jealous, England began to waver, and there was not a power in Europe upon whom Lewis XIV. could heartily rely. The army of Brandenburg commanded by the elector in person, and the forces of the empire under the famous Montecuculi, joined near Heidelberg, and composed a body of 40,000 men. Turenne, now appointed generalissimo of the king's army on his Majesty's return to Paris, marched to oppose the enemy's passing the Rhine. For three whole months were the elector and Montecuculi employed in abortive attempts to effect a passage at Mentz, Coblintz, Strasburgh, and other places. This answered the purpose of making a powerful diversion in favour of the Dutch, though they could not accomplish their design of joining the prince of Orange. After repeated disappointments, the imperial army directed its march to Westphalia; and Turenne followed, in order to keep the bishop of Munster steady to his engagements. For half the campaign, he, with a body of 16,000 men, baffled every stratagem of the elector and Montecuculi, the latter the most renowned

general.

general of the empire, at the head of an army near triple his strength. He obliged them to go into winter-quarters, in a country harassed and exhausted; and confirmed the bishop of Munster in the alliance of France, at the very time he was on terms with the emperor. He obliged the elector of Brandenburg, who took the chief command during Montecuculi's illness, to abandon the siege of Werle; took Unna, Kamen, Altena, Berkembaum, and several other towns and fortresses. By continuing his operations, he forced the elector out of his winter-quarters again into the field, chased him from post to post, until he obliged him to quit Westphalia, repass the Weser, and retire with precipitation into the bishopric of Hildesheim. After taking possession of all the elector's towns in Westphalia, he pursued him into the bishopric of Hildesheim; and at length, by mere dint of superior genius, forced him to seek shelter in his hereditary dominions. All this was effected after Louvois had appointed the marshal's army quarters in Alsace and Lorraine, amidst the rigours of a severe winter, opposed by a superior enemy, by the artifices of Louvois, and seconded only by his own prudence, and the affections of his troops, which he maintained in defiance of all the difficulties, hardships, and dangers, they encountered. It was indeed supposed, that Montecuculi was prevented from giving Turenne battle by the remonstrances of prince Lobkowitz, the emperor's ambassador, influenced by the gold of Lewis. Certain indeed it is, that Montecuculi's illness arose from his chagrin at seeing all his projects frustrated by the unsteady dilatory conduct of the court of Vienna. Lewis's negotiations disturbed Europe no less than his arms. His tools and creatures swarmed in every court. Leopold could not be prevented from declaring in favour of Holland; but his ministers were bought off from seconding the emperor's intentions. The whole English nation exclaimed against the alliance of their king with France; but Charles stood in need of French gold to supply his extravagance and profligacy. The elector of Bavaria had indeed been compelled by Lewis to retire to his capital; but it was by dint of intrigue that he was forced from his alliance with Holland, and constrained to sign a peace with France.

While Turenne was thus employed on the Rhine, Condé having recovered of his wounds, returned to the command of the army in Holland. He besieged and took Maastricht in 13 days. Having repaired the fortifications, he proposed making himself master of several other towns; but the inundations every-where stopped his course. All his attempts to draw off the waters were in vain; and he was forced to content himself with preserving, without pretending to extend, the king's conquests.

Whatever glory the king might have acquired by land, certain it is that the conduct of his admirals deserved equal praise with that of his generals. In little more than 12 months the French were taught the art of naval war. Before, they fought ship to ship; but understood nothing of those evolutions by which whole fleets imitate the movements of armies. The duke of York, afterwards James II. invented the method of giving all orders at sea by means of signals: this and every other part of the art the French borrowed from the English; and became so apt scholars, that they

ventured to give battle to the Hollanders, the great rivals of the English on that element. Their fleet, amounting to 40 sail, besides fire-ships, joined to the English, gave battle three different times to the Dutch. De Ruyter gained additional glory in these engagements; and D'Edrees, the French admiral, gained the eitem of De Ruyter.

In the mean time Spain declares in favour of the Dutch; and prevails upon the emperor to act more heartily in the cause of Holland, and defence of the liberties of Europe. The prince of Orange was reinforced by 10,000 Spaniards, sent to him by the governor of the Low Countries. Philip had concluded a treaty with the States at the Hague, whereby he declared war against France, engaged the emperor to make a powerful diversion on the Rhine, stipulated not to accept of peace before the Dutch had retrieved all their losses, and obtained from them a promise to listen to no terms of accommodation before his Catholic majesty was reinstated in all his possessions in the Low Countries, previous to the peace of the Pyrenees. Montecuculi was ordered to advance with 30,000 men to Franconia; and Turenne, joining the troops of Cologne and Munster, passed the Main, and took post in the electorate of Mentz. The prince of Orange receiving no impediment from Condé, who was forced on account of the inundations to repass the Meuse, thought this a proper time for action, as the enemy had no considerable forces in the heart of the United Provinces. He ordered some troops to file off secretly to Amsterdam and Muiden; lined with infantry the intrenchments which secured the passage to Holland; and to deceive the duke of Luxemburg, who commanded in Utrecht, sent some forces by sea to attack Bowmel. The duke, not penetrating the prince's design, came to succour the place; and William finding his stratagem succeed, marched to Naerden, and with 25,000 men invested and took the place before the duke could provide for its security. Upon this success, the Dutch took courage, fortune inclined in their favour, and in a short time all the horrors of war were removed from the interior parts of the United Provinces to the Spanish Netherlands. Neither the experience nor consummate address of Turenne, the genius of Vauban, or the indefatigable vigilance of Louvois, could repair the error committed in ruining the army to garrison the conquered towns. Even Condé's fire seemed extinguished in the waters with which the Dutch had drowned their country. Instead of penetrating farther, he was obliged to retreat. Turenne could not prevent the junction of Montecuculi and the prince of Orange, nor the loss of Bonne. This junction, and the declaration of Spain, obliged the armies of France to abandon the three provinces with still more rapidity than they had conquered them. The triumphal arch at St Denis was hardly erected as a monument of Lewis's victories, before the fruits of those victories were relinquished. In a word, the parliament of England would no longer suffer Charles to be the mercenary tool of France; the late ill success cooled the elector of Cologne and bishop of Munster in their friendship; and Lewis, forsaken by all his allies, found himself under the necessity of maintaining singly a war against the empire, Spain, and the United Provinces.

From that time the United Provinces have been
d/Ria-

Britain,
no 339, 340

distinguished among the European nations as a very considerable maritime and commercial power. Their connection with Britain by the revolution in 1688, when William III. stadtholder of Holland became king of this island, brought on a much closer connection between the two nations than had ever taken place before. By means of this connection William formed a plan of humbling his great adversary Lewis XIV. who had for lately brought his country to the verge of ruin. For this purpose he renewed the war in 1689, and commanded the army in person. However, he was overmatched by the abilities of Luxembourg the French general; who opposed him, and obliged him to conclude a peace in 1697. His enmity to the French king, however, was not yet extinguished. The remaining part of his life he employed in forming a most powerful confederacy against that monarch; and so much was he wrapped up in this project, that even in his dying moments it seemed to prevail over every other consideration *. His measures, however, were adopted by his successor Queen Anne; and the French monarch had nearly sunk under the united efforts of the forces of Britain, Holland, and Germany, headed by the experienced generals Marlborough and Eugene. But at last the whole plan was disconcerted by a revolution in the British ministry; the Dutch were disappointed in the moment of their expectations, and obliged to consent to the peace of Utrecht, which left them exposed to the attempts of France as much as ever. A barrier composed of a great number of fortified towns was indeed granted them; but barriers of this kind are a slender defence against the modern improvements in war. In the war of 1739, these towns were taken one after another by Marshal Saxe, who thus revenged the exploits of the duke of Marlborough; while the Dutch and British army commanded by the late duke of Cumberland, were driven from place to place, without being able to make one successful effort from the beginning of the war to the end of it. See BRITAIN, no 342—423.

It is probable that the bad success of this war cooled the affections of the Dutch towards Britain so much, that ever since they have acted rather as concealed enemies than friends. In the war of 1755, their attachment to France was evident; and in the last, it proceeded to such an height, as to oblige the British ministry to declare war against them. The issue of this war is still fresh in our memories. A single naval engagement was the only event of consequence that took place, and showed that both were formidable antagonists to each other. The republic still possesses dominions of great consequence in the East Indies, with some portion of South America, and by constant application to commerce may perhaps be reckoned the richest nation in Europe.

88
Climate,
&c of the
United
Provinces.

The seven United Provinces being in great part surrounded by the sea, lying low, and abounding in marshes, have a damp and unwholesome air. Rains and fogs are frequent; and the gout, scurvy, rheumatism, and agues, very common, and difficult of cure. The effects of human industry here are wonderful in the dykes and dams erected for defending the country against the inundations of the sea, and in ditches, canals, mills, and sluices, for draining the marshes. The quantity of grain produced is not sufficient for

United
Provinces.

home consumption; but the pastures in the marshes are so rich, that they can spare a great deal of butter and cheese for exportation. They have also a good breed of sheep, whose wool is highly valued. There is turf, madder, tobacco, some fruit, and iron; but all the pit-coal and timber used in this country, and indeed most of the necessaries of life, are imported. All the provinces either lie upon, or communicate with, the North-sea, by means of that called the *Zuyder*, or *Sourh-sea*; which was formed partly by the Rhine's right branch, then increased by the Vecht, which has now another outlet, overflowing the low swampy grounds through which it passed; and partly by the sea's breaking in, in the 13th century, and overflowing a large tract of ground contiguous to that before laid under water by the Rhine. The principal rivers are the Rhine, the Meuse, the Scheld, and the Vecht. The first is divided into several branches, one of which joins the Old IJssel, and after that falls into the *Zuyder-sea*; another named the *Leek*, at the village of Krimpen, mingles with the Meuse; a third, called the *Crooked Rhine*, is branched out at Leyden into canals, of which one runs into the lake of Haarlem, and another loses itself in the sand hills between Catwyk on the Rhine, and Catwyk on the sea; and a fourth, called the *Waal*, falls into the Meuse over against Workum. The Meuse, after dividing itself into two branches, and again uniting these, falls into the North-sea, below Rotterdam. The Scheld below Antwerp divides itself into two branches, called the *Western* and *Eastern Scheld*; the first separating Flanders from Zealand; and the other, running north by Bergen-op-Zoom, and afterwards east, between the islands of Beveland and Schowen, falls into the sea a little below. The Vecht runs from east to west through the province of Overijssel, and falls into the *Zuyder-sea*. There are many smaller rivers that join these, and a vast number of canals; yet there are few good harbours in the provinces. The best are those of Rotterdam, Helvoetsluis, and Flushing. As to the harbour of Amsterdam, it is indeed one of the largest and safest in Europe; but there is a bar at the entrance of it, over which large vessels cannot pass without being lightened or unloaded. There are no mountains in these provinces; and the only lake, properly so called, is that of Haarlem. The provinces are extremely well cultivated, and very populous; especially that of Holland, which, in this respect, perhaps has not its equal in the universe. The towns are very agreeable, being kept clean, and having canals in the middle of the streets, planted with trees. The number of inhabitants is computed at about 200,000. The animals here are much the same as in England; but their horses and horned cattle are of a larger size. Storks build and hatch on their chimnies; but, being birds of passage, they leave the country about the middle of August, with their young, and return the February following. It is said there are some wild boars and wolves here; and that neither oysters nor herrings are to be found upon the coast: but of other fish, they have the several sorts, both in their seas and rivers, that we have in Britain.

The established religion here is the Presbyterian, or Calvinism; none but Presbyterians are admitted into any office or post in the government, excepting the army;

89
Religion.

United
Provinces.

army; yet all religions and sects are tolerated, and have their respective meetings or assemblies for public worship, among which the Papists and Jews are very numerous. There are five universities in the provinces, viz. those of Utrecht, Leyden, Franeker, Groningen, and Harderwic; but the three last are inconsiderable. The dissenters in England often send their children to these universities for education. Before the Reformation there was an archbishop at Utrecht, who had for his suffragans the bishop of Deventer, Groningen, Middleburg, Haarlem, and Lewarden. The language here is a dialect of the German, but French is much spoken by the better sort.

90
Commerce,
&c.

With regard to the commerce of this country, their East-India company have had the monopoly of the fine spices for more than 100 years, and is the most opulent and powerful of any in the world. Though the country itself produces very few things, yet almost all the products and commodities of the globe may be found here, nearly as cheap as in the countries where they are made or produced. A vast variety of manufactures are carried on in the provinces, and with extraordinary skill and diligence; and a great number of hands are employed, and much wealth acquired, by the herring, cod, and whale fisheries. No nation has hitherto equalled them in the curing of herrings; those cured at Glasgow, in Scotland, are thought to come nearest to them. About 150 sail are annually employed in the whale fishery, and about 200 in the herring. The profits of the latter, in a good year, after all deductions, are thought to amount to 200,000 Holland guilders. The principal manufactures here are those of linen, paper, and earthen-ware of all sorts. Ship-building also employs vast numbers of hands. The trade of this country, however, upon the whole, is said to be upon the decline; owing partly to a decline of their ancient parsimony and industry; but chiefly to the improvement of manufactures, trade, and navigation, in other countries.

91
Constitu-
tion.

Most of the towns in the several provinces are little republics, whose deputies, with the nobility, compose the states thereof; and the deputies of the provinces, in like manner, compose the states-general. Every town or province may send as many deputies as they please to the assemblies of the provincial states, or states-general; but those of each town or province have but one voice, and preside by turns. No resolution taken by the states-general is of any force, till it is confirmed by the several provinces. The legislative power in the towns is vested in the senates; and the executive in the burgomasters, syndics, &c. The states of the provinces are styled, Noble and Mighty Lords; but those of Holland, Noble and Most Mighty Lords; and the states-general, High and Mighty Lords, or the Lords the States-general of the United Netherlands, or their High Mightinesses. Besides the states-general, there is also a council of state, consisting of deputies from the several provinces, making twelve in all; of which Holland sends three; Gelderland, Zealand, and Utrecht, two a-piece; and Friesland, Groningen, and Overysel, one. In this council every deputy presides a week by turns, and the stadtholder has a decisive voice when the votes happen to be equal. The principal affairs that come under their delibera-

United
Provinces.

tion, are those relating to the army and finances. The stadtholder is also president of the states in every province, but has no seat in the states-general. One dissenting voice in the provincial states prevents their coming to any resolution. From the death of William III. prince of Orange and king of England, there had been no stadtholder, at least for the provinces of Holland, Zealand, and West-Friesland; but these also, in 1747, upon the French breaking into Dutch Flanders, made choice of William-Charles-Henry-Frifo, prince of Orange. The stadtholdership was at the same time made hereditary to his heirs male and female, provided the latter did not marry the son of a king, or a Papist. The stadtholder's powers and prerogatives are very considerable: in particular, he seems directly, or by his influence, to have the nomination of the magistrates, deputies, and most of the officers civil and military. In short, though he has not the title, he has more real power and authority than many kings; for besides the influence and revenue he derives from the stadtholdership, he has several principalities and large estates of his own.

With respect to the administration of justice in this country, every province has its tribunal, to which, except in criminal cases, appeals lie from the petty and country courts; and it is said, that justice is nowhere distributed with more impartiality.

The taxes in these provinces are so many, and so heavy, especially in Holland, that it is not without reason asserted, that the only thing that has escaped taxation there is the air they breathe. The ordinary revenues of the republic are computed at between two and three millions sterling annually. Out of 100 guilders, the province of Holland contributes 58; and consequently above one half of the whole public expences. For the encouragement of trade, the duties on goods and merchandise are said to be exceeding low.

With respect to their land-forces in time of peace, they seldom exceed 40,000, and very often fall short of that number. They employ a great many foreigners in their service; and in time of war, hire whole regiments of Germans. The chief command of the army is vested in the stadtholder, under whom is the field-marshal general. In 1756 the expences of the army amounted only to 9,765,004 guilders. No nation in the world can so quickly fit out a formidable fleet than the Dutch; having always vast quantities of timber prepared for building of ships, and such numbers of ship-carpenters and mariners; however, in times of peace, they usually have no more than 30 in commission, for the protection of their trade in the Mediterranean, and to convey the homeward-bound Indians, &c. Their navy is under the direction of the five admiralty colleges, who, to defray the charges thereof, levy the duties on exports and imports.

As to the character of the Dutch, the boors or husbandmen are industrious enough, but heavy, and slow of understanding. The seamen are a plain, blunt, but rough, surly, and ill-mannered sort of people. Their tradesmen are something sharper, and make use of all their skill to take advantage of those they deal with. Every class of men are extremely frugal. All appetites and passions run lower and cooler here than in other countries, avarice excepted. Quarrels are very rare;

94
Character.

rare; revenge is seldom heard of; and jealousy scarcely ever known. It is very uncommon for any of them to be really in love, or even to pretend to it; nor do the women seem to care whether they are or not. People converse pretty much upon a level here; nor is it easy to distinguish the man from the matter, or the maid from the mistress, such liberties do they allow their servants, or rather are obliged to allow them; for they may not be struck or corrected by them, but the dispute must be left to the magistrate. The Dutch are tall and strong-built; but both men and women have the grossest shapes that are to be met with any where. Their garb, except among the officers of the army and some few others, is exceeding plain, and the fashions change as seldom as in Spain. The men are addicted to drinking; which some think necessary in this foggy air, both for their health and the improvement of their understandings. Among their diversions, that of skating in winter is one of the chief. It is amazing to see the crowds in a hard frost upon the ice, and their great dexterity in skating; both men and women darting along with inconceivable velocity. The Dutch are remarkable for their cleanliness: nothing can exceed the neatness of their houses, towns, and villages. Many of them have distinguished themselves by their learning, and some even by their wit and ingenuity; witness Erasmus, Grocius, &c. The Dutch excel also in painting and engraving; and some of them have been no contemptible statuary.

UNITY, in poetry. There are three unities to be observed, *viz.* the unity of action, that of time, and that of place. In the epic poem, the great, and almost the only, unity, is that of the action. Some regard indeed ought to be had to that of time; for that of place there is no room. The unity of character is not reckoned among the unities. See POETRY, chap. ii. 24, &c.

UNIVERSAL, something that is common to many things; or it is one thing belonging to many or all things.

UNIVERSE, a collective name, signifying the whole world; or the assemblage of heaven and earth, with all things therein. See ASTRONOMY and GEOGRAPHY.

UNIVERSITY, a collective term applied to an assemblage of several colleges established in a city, wherein are professors in the several sciences, appointed to teach them to students, and where degrees or certificates of study in the divers faculties are taken up.

In each university four faculties are usually taught, theology, medicine, law, and the arts and sciences.

They are called *universities*, or *universal schools*, by reason the four faculties are supposed to take in the whole compass of study.

Universities had their first rise in the XIIth and XIIIth centuries. Those of Paris and Bologna pretend to be the first that were set on foot; but they were on a different footing from the universities among us.

The universities of Oxford and Cambridge seem entitled to the greatest antiquity of any in the world; and Balliol and Merton colleges in Oxford, and St Peter's in Cambridge, all made colleges in the XIIIth century, may be said to be the first regular endowments of this kind in Europe.

The universities of Scotland are four, *viz.* those of

St Andrews, Aberdeen, Edinburgh, and Glasgow. University. See EDINBURGH, &c.

UNIVERSITY-COURTS, in England. The two universities enjoy the sole jurisdiction, in exclusion of the king's courts, over all civil actions and suits whatsoever; where a scholar or privileged person is one of the parties; excepting in such cases where the right of freehold is concerned. And then by the university charter they are at liberty to try and determine, either according to the common law of the land, or according to their own local customs, at their discretion; which has generally led them to carry on their process in a course much conformed to the civil law.

This privilege, so far as it relates to civil causes, is exercised at Oxford in the chancellor's court; the judge of which is the vice-chancellor, his deputy, or assessor. From his sentence an appeal lies to delegates appointed by the congregation; from thence to other delegates of the house of convocation; and if they all three concur in the same sentence, it is final, at least by the statutes of the university, according to the rule of the civil law. But if there be any discordance or variation in any of the three sentences, an appeal lies in the last resort to judges delegates appointed by the crown under the great seal in chancery.

As to the jurisdiction of the university-courts in criminal matters, the chancellor's court at Oxford, and probably also that of Cambridge, hath authority to try all offences or misdemeanors under the degree of treason, felony, or mayhem; and the trial of treason, felony, and mayhem, by a particular charter, is committed to the university jurisdiction in another court, namely, the court of the lord high steward of the university.

The process of the trial is this. The high steward issues one precept to the sheriff of the county, who thereupon returns a panel of 18 freeholders; and another precept to the bedells of the university, who thereupon return a panel of 18 matriculated laymen, *laicos privilegio universitatis gaudentes*: and by a jury formed *de medietate*, half of freeholders and half matriculated persons, is the indictment to be tried; and that in the guildhall of the city of Oxford. And if execution be necessary to be awarded in consequence of finding the party guilty, the sheriff of the county must execute the university process; to which he is annually bound by an oath.

VOCABULARY, in grammar, denotes the collection of the words of a language, with their significations, otherwise called a *dictionary*, *lexicon*, or *nomenclature*. See DICTIONARY.

A vocabulary is properly a lesser kind of dictionary, which does not enter so minutely into the origin and different acceptations of words.

VOCAL, something that relates to the voice or speech: thus vocal music is that set to words, especially verses, and to be performed by the voice; in contradistinction to instrumental music, composed only for instruments, without singing.

VOCATIVE, in grammar, the fifth state or case of nouns. See GRAMMAR.

VOETIUS (Glabri), an eminent divine of the 16th century, was professor of divinity and the Oriental tongues at Utrecht, where he was also minister. He assisted at the synod of Dort; and died in 1676, aged 87. He wrote a great number of works; and was the

declared enemy of Des Cartes and his philosophy. His followers are called *Voetians*.

Voetius had two sons, *Daniel* and *Paul*, who also wrote several works. *John Voetius*, the son of Paul, was doctor and professor of law at Herborn: he wrote a commentary on the *Pandects*, which is esteemed, and other works on law.

VOICE, a sound produced in the throat and mouth of an animal, by an apparatus of instruments for that purpose.

Voices are either articulate or inarticulate. Articulate voices are those whereof several conspire together to form some assemblage or little system of sounds: such are the voices expressing the letters of an alphabet, numbers of which joined together form words. Inarticulate voices are such as are not organized, or assembled into words; such is the barking of dogs, the braying of asses, the hissing of serpents, the singing of birds, &c.

The formation of the human voice, with all the varieties thereof observed in speech, music, &c. makes a very curious article of inquiry; and the apparatus and organism of the parts administering thereto, is something exceedingly surprising. Those parts are the trachea or wind-pipe, through which the air passes and repasses into the lungs; the larynx, which is a short cylindric canal at the head of the trachea; and the glottis, which is a little oval cleft or chink left between two semicircular membranes stretched horizontally within the larynx; which membranes, though capable of joining close together, do generally leave an interval, either greater or less, between them, called the *glottis*. A particular description of each part may be seen in *ANATOMY*, Part IV.

VOICE, in grammar, a circumstance in verbs, whereby they come to be considered as either active or passive; *i. e.* either expressing an action impressed on another subject, as, *I beat*; or receiving it from another, as, *I am beaten*. See *GRAMMAR*.

VOICE, in matters of election, denotes a vote or suffrage.

VOICE, in oratory. See *DECLARATION*; *READING*, n° xii.; and *ORATORY*, n° 129, 131.

VOLANT, in heraldry, is when a bird, in a coat of arms, is drawn flying, or having its wings spread out.

VOLATILE, in physics, is commonly used to denote a mixed body, whose integral parts are easily dissipated by fire or heat; but is more properly used for bodies whose elements or first component parts are easily separated from each other, and dispersed in air.

VOLATILE *Alkali*, a name given to one of the primary or elementary salts, the basis of all those which go by the name of *ammoniacs*. It is produced chiefly from animal-substances, especially urine, either by distillation with a strong heat, or by putrefaction. In its pure state it is a transparent elastic fluid like common air, but lighter in a considerable proportion; and in this state Dr Priesley has given it the appellation of *alkaline air*. It unites very readily with fixed air, and with all kinds of acids, forming with them various neutral salts according to their different natures. It unites also with water, which will imbibe one third of its weight of alkaline air. The mixture then is a caustic volatile spirit, the strongest that can be made, which unites with acids without any effervescence. If

fixed air is added, the spirit then contains volatile salt, and is said to be mild; though in fact it is now partly changed into a neutral saline mixture along with a quantity of caustic spirit. If a true caustic spirit is exposed to the air, part of the alkali will fly off; but part is also neutralized by the fixed air which it attracts from the atmosphere. The salt formed by an union of fixed air with volatile alkali is the most volatile of all the ammoniacal salts, and may be made perfectly neutral, though it is easily super-saturated with alkaline air, and is then extremely pungent. In this state it is called *volatile salt*, and is used in smelling-bottles; but the superfluous quantity of alkaline air soon flies off, and the salt remains neutral as before. Alkaline air in large quantities is fatal to animals, though in a small proportion it is a medicine of great efficacy in cases of fainting. It is very caustic; dissolves oils, and renders them soluble in water; prevents putrefaction; and is inflammable, but burns without any explosion. For the chemical properties of the volatile alkali, see *CHEMISTRY*, n° 319, & seq.

VOLATILISATION, the art of rendering fixed bodies volatile, or of resolving them by fire into a fine subtle vapour or spirit which easily dissipates and flies away. All bodies, even the most fixed, as gold, may be volatilized, either of themselves, or with the admixture of some volatile substance or spirit, by distillation or sublimation.

VOLCANO, or VULCANO, a name given to several parts of the earth whence flames, smoke, stones, cinders, &c. are sometimes thrown out with astonishing violence and in prodigious quantity. The name is borrowed from VULCAN the Heathen god of fire, who was fabled by the poets to have his work-shop under Mount *Ætna*, where he, with the assistance of the Cyclops his servants, forged thunderbolts for Jupiter.

The greater part of the known volcanoes are situated under high mountains, which they perforate by means of their internal heat, and throw out such immense quantities of melted and burning hot matter, from the bowels of the mountain, that it is wonderful how it continues to support itself, and is not at once precipitated into the huge caverns which must be occasioned by the disgorging such immense quantities of matter. The very summit of volcanoes indeed does from time to time fall into the abyss below; but this is soon repaired again by the quantity of stones, cinders, and ashes, thrown out of the volcano, which form a conical mount, hollow like a funnel in the inside, and having an hole in the middle which leads directly down to the abyss whence the fire proceeds. This conical mount is supported all the way down by the stones and other matter heaped up on each side of the spiracle or chimney through which the fire of the volcano passes. But in process of time the vehemence of the heat, or its long continued action, wears away those supports, and the top again falls in, and soon after is renewed as before. But though the summit of volcanoes thus very often falls in, we seldom or never hear of a burning mountain falling down from the foundation. On the contrary, *Ætna*, though it has continued to burn from time immemorial, is still a very high mountain. *Vesuvius* also continues much of the same height as ever, though its summit, and even great part of the mountain itself, has been known to fall

of the
situation
and
form of
volcanoes

Volcano. fall in. However, it must be remarked, that though volcanoes are generally seated under high mountains, this is not always the case. In the Mediterranean, a burning island arose in the beginning of the present century, upon which there was no eminence of any considerable height. In the island of Tanna, in the South Sea, also, Mr Forster mentions a volcano whose height was much less than that of many hills in the neighbourhood.

3
Plumes of
their eruption
uncertain.
Though volcanoes generally emit a hot sulphureous and suffocating steam, yet they by no means cast forth flames at all times with violence. This happens only at uncertain intervals of sometimes more than a century together. Nay, sometimes even the emission of the above-mentioned kind of steam ceases, the crater or chimney of the volcano is covered over with earth and vegetables, and it is forgot that ever any eruption took place. This appears to have been the case with Vesuvius before the time of Pliny; for at that time nobody seems to have apprehended the least danger; though it is now pretty certainly determined that many eruptions had happened before this time. The signs of an approaching eruption are enumerated under the article *Ætna* so fully, that little remains to be added here. It would seem however, from the accounts of Sir William Hamilton and Mr Brydone, that neither the volcanoes of *Ætna*, Vesuvius, nor Stromboli, are ever in a state of perfect quietness. Smoke continually issues from them, and explosions and other noises are heard within them. Mr Brydone particularly mentions a small mountain on the side of *Ætna*, which disturbed him in the night-time with frequent explosions like the noise of heavy cannon fired at a distance, though the mountain was then as quiet as it is almost ever known. Mr Hamilton mentions it as a common remark at Naples, that Vesuvius *grumbles in bad weather*; which he explains by supposing that the sea forces itself into some of the caverns under the mountain, and which are at all times of a glowing heat, whence arise those explosions and strange kinds of sounds above-mentioned: but we can scarce suppose this to be peculiar to Vesuvius; nor is there any certainty of a communication between that mountain and the sea. Mr Raspe indeed supposes the sea-water to be necessary for the accension of volcanoes; but of this he brings no proof. It is certain indeed that many of them are below the bottom of the sea; but it seems most probable that the water has not access, or but in small quantity, to the place whence the fire originates. Mr Forster, from more certain observation, concludes, that volcanoes are exasperated by the falling of rain. This he took particular notice of in the volcano in the island of Tanna, and suspects that rain excites the explosions by increasing the fermentation of the mineral substances within the mountain.

4
Vesuvius
most noisy
in bad weather.
The force with which a volcano explodes seems to be the greatest hitherto known in nature. So great indeed is this force, that we must of necessity suppose the resistance of the air to be exceedingly lessened before the projected materials. Under the article *GUNNERY*, it is shown how great this resistance is, and what an effect it has upon globes of solid iron. Upon irregular masses of rock, then, and much more upon streams of liquid lava, the resistance must be such as to stop their motion almost as soon as it began.

5
Conjectures
concerning
the accension
of volcanoes.
6
Prodigious
force of volcanoes.
Nevertheless, in the great eruption of Vesuvius in 1779, Sir William Hamilton informs us, that a stream of lava of an immense magnitude was projected to the height of at least 10,000 feet above the top of the mountain; and if to this we add the depth of the source whence this lava was derived, the force by which it was impelled must exceed our imagination. Indeed, let us suppose the cause to be what we will, had the air exerted its resisting power upon this lava as it does on a cannon-ball, the force necessary to have carried it to that amazing height must have dashed the stream in pieces at its first emission from the mouth of the volcano. Either the extreme heat of the lava, therefore, or some other cause must contribute to keep off this resistance, without which we cannot suppose that it could have reached to such an height, much less could the lighter materials, ashes, cinders, &c. have arisen to an height sufficient to carry them to the distance of 100 miles from the mountain, which we are assured was the case at that time.

7
There are no phenomena in nature whose cause seems more difficult to be explained than volcanoes. The fermentation of pyrites, of sulphur and iron, the explosion of nitre, of aqueous steam violently heated, or of air pent up and greatly rarefied, have all been of volcanic thought of to explain them, but with very little success. Dr Woodward and others have recourse to a central fire which they suppose to exist in the bowels of the earth, and suppose that volcanoes are so many spiracles or chimneys to prevent it from destroying the whole world.

8
It must, however, be very evident, that the immense force which we observe in volcanoes cannot by any means be accounted for from any such principles. It is impossible that beds of pyrites can be so totally inexhaustible as to remain for thousands of years under, or nearly under, the same part of the surface of the earth. And as to nitre, it is never found in a fossil state, nor indeed can we conceive that such quantities of nitre can exist under any one part of the surface as would be sufficient for a single explosion: besides, nitre does not explode instantaneously, unless it is thoroughly mixed with sulphur and charcoal in order to convert it into gun-powder; an operation which cannot take place in the bowels of the earth. As little can we suppose those eruptions owing to the expansion of aqueous steam; for though this will in some cases explode with great violence, yet in others it seems to be in a manner totally deprived of that power. With melted lead, copper, or salts, it explodes with the utmost fury, even when water in a very small quantity is thrown upon the surface of such substances; yet on the surface of melted glass, which is much hotter than any of them, water will not explode, but evaporates quietly, seemingly kept at some distance from the surface of the glass by the violent emission of steam from its under part. Nay, with this violent heat, it does not even appear to boil; but gradually lessens in its dimensions, until at last it quite disappears. Indeed, if we suppose water intimately mixed and dispersed in small quantities through the substance of melted glass or any similar substance, no doubt a very violent explosion will take place; but in this case the matter, instead of being thrown up in a full stream, would be scattered all around in an im-

Volcano.

menſe number of ſmall drops. Indeed we cannot conceive how any ſuch intimate mixture could take place; for if we ſuppoſe any large collections of water to exit under ground at the ſame time that a lava is by ſome unknown means melted in ſuch a manner as to come in contact with it, either the water muſt fall upon the lava, or the lava into the water. If the water falls upon the lava, no exploſion will take place, as has been already ſhown; and if the lava falls into the water, the liquid muſt no doubt be heated boiling hot, and the ſteam diſſipated with thoſe noify exploſions mentioned under the article *ΑΡΤΗΑ*, when a lava of that mountain ran into the ſea. On this ſuppoſition, however, the lava could never be projected above the mountain; much leſs can we ſuppoſe that ſolid rocks ſhould be moved from their places, and thrown to great diſtances, as experience ſhows them to be. In the eruption of Veſuvius in 1779, Sir William Hamilton meaſured one which was 108 feet in circumference and 17 feet high, and which was thrown to the diſtance of more than 1300 feet from the crater of the volcano. If we ſuppoſe this ſtone to have been only twice as heavy as water, it muſt have weighed conſiderably more than 700 tons; and the projectile power employed to throw this to ſuch a diſtance muſt have exceeded any thing we can conceive, almoſt, of the force of gun-powder itſelf.

Difficulties
in aſcertain-
ing the true
cauſe.

Indeed, when we conſider the immenſe power exerted by volcanoes, we can ſcarce find any thing in nature to which it can be aſcribed. What only ſeems to reſemble it is the exploſions of inflammable air in mines, and of which an account is given under the article *DAMP*s. But as it is impoſſible to account for the continual generation of this air, which we know muſt be deſtroyed by every exploſion, we cannot have recourſe to this agent; nor, though electricity ſeems to be very much concerned in volcanoes, are we acquainted with any laws according to which that fluid acts, by which a ſucceſſion of violent exploſions could be occaſioned. The primary conſideration, however, in attempting to account for the phenomena of volcanoes, is the means by which the fire is originally kindled, becauſe upon this, ſome-how or other, all the reſt of the phenomena depend. This, from what has been already obſerved, cannot be occaſioned by fermentations of metalline, mineral, or ſaline ſubſtances, which in time would wear out; but muſt depend on ſome inexhauſtible cauſe.

Fire of vol-
canoes origi-
nally kind-
led by the
electric
fluid,

The only inexhauſtible ſource of fire which we are acquainted with is the electric fluid, by means of which every degree of heat, even to that which vitrifies gold and platina, may be excited. From the many articles in this work, where the nature of the electric fluid has been conſidered, it muſt appear very probable that it is no other than the light of the ſun himſelf abſorbed by the earth, pervading every part of it, receiving new motions, and becoming ſubject to new laws, in conſequence of this abſorption, as if it were different fluid. As the ſun perpetually ſends down an immenſe quantity, great part of which is ſtill abſorbed, it is impoſſible that ſuch an abſorption can take place without an emiſſion of an equal quantity ſomewhere or other. The outlets to this fluid are innumerable; but by various cauſes many of theſe may occaſionally be ſtopped. In this caſe it is plain, that the fluid muſt move with greater velocity through thoſe which remain

open. But it has been ſhown, under the article *ELECTRICITY*, n° 79. and *HEAT*, n° 9. that the violent motion of the electric fluid through any ſubſtance is heat; that when this fluid converges to a centre, or diverges from one, heat always takes place in the central point, and that more or leſs violent according to the quantity of fluid which thus converges or diverges. If then, from any cauſe, the electric matter diffuſed through a very large portion of the earth ſhould converge towards one particular ſpot on the ſurface, then that ſpot would undoubtedly be heated, or perhaps ſet on fire; and if a ſufficient quantity of electric matter ſhould conſtantly be directed in this manner, we muſt eaſily ſee that the heat would be continual. Hence may be underſtood the origin of *ſolfataras*, or ſpots of earth which have a continual heat in them, and of hot ſprings. But if this violent flux of electric matter ſhould by any means be interrupted and renewed at uncertain intervals, we ſee, in that caſe, the heat muſt occaſionally increaſe and decreaſe, without any cauſe viſible to thoſe who dwell near the ſpots above-mentioned. In volcanoes, however, it is probable that the flux of electric matter always continues to a very conſiderable degree, but occaſionally is increaſed in ſuch a manner as to melt down the earth, ſtones, and mineral ſubſtances through which it paſſes into the ſemivitrified compound called *lava*.

We cannot indeed, as yet particularly know the cauſes by which this electrical flux is at all times occaſioned. In general, we are certain, that whatever has a tendency to ſolicit the matter to the ſurface, will increaſe the violence of an eruption; and whatever can increaſe it after it has begun, will alſo contribute to bring it on originally. This will happen when the preſſure of the atmophere directly over the mountain is leſſened; when a cloud paſſes over it whoſe electricity is oppoſite to that of the mountain itſelf, or which, by acting as a conductor, may facilitate the eſcape of the confined electric matter; or it will readily happen if by any means the ſurface of the mountain and of the earth round it is rendered a better conductor than uſual. But above all, the ſtate of electricity in the neighbouring earth and air muſt contribute towards the bringing on an eruption, or increaſing one which is already begun. Under the article *EARTHQUAKE*, n° 29. it has been ſhown, that when there is a perfect equality between the electricity of the earth and of the atmophere, there is then great danger of a conſuſion, becauſe the electric matter can neither get into the atmophere from the earth, or into the earth from the atmophere. It muſt therefore ſtagnate altogether, and be ready to burſt out on all ſides, when the preſſure upon it becomes ſufficiently ſtrong. In ſuch circumſtances, if there happens to be a volcano in the neighbourhood, it is probable that it will be ſet on fire, or perhaps a new volcano may be produced on this occaſion.

Theſe cauſes ſeem to be ſufficient for the production of volcanoes, and ſetting them on fire from time to time, as uſually happens with them; though no doubt there may be others much more unknown to us which take place in the bowels of the earth itſelf; but theſe are entirely concealed from us, we can only gueſs at their exiſtence. But that all the above-mentioned cauſes do contribute towards the eruption of burning mountains experience evinces. Sir William Hamilton

men.

Volcano. mentions it as a common observation, that the inward explosions of Vesuvius increase during bad weather, when we know that the pressure of the atmosphere is lessened, and the defending vapours serve as conductors to the electric fluid. The same gentleman informs us, that, on the 7th of August 1779, as he was observing Vesuvius, a collection of thunder-clouds passed directly over its summit, and mingled with the sulphureous and mineral clouds of smoke, cinders, and ashes, which were then piled up to an amazing height over its top. "At this moment (says he) a fountain of fire was shot up to an incredible height, casting so bright a light, that the smallest objects could be clearly distinguished at any place within six miles or more of Vesuvius." Thus we see that these clouds acting either by their conducting power as aqueous vapours, or by an electricity opposite to that of the volcano, solicited a vast discharge of the fire as soon as they came directly over it. Mr Forster's observation, that the volcano in the island of Tanna took fire after rain, has been already mentioned; and the cause will now be apparent, namely, that by this means the surface of the ground all round was rendered a much better conductor than before, and perhaps supplied with a greater quantity of electricity, the passage of which to the volcano was now free, in consequence of which it took fire and burnt violently till this supply was again exhausted. Lastly, it is well known that some countries which were formerly very subject to earthquakes, have been freed from these destructive phenomena by the breaking out of a volcano. In the time of earthquakes also, temporary volcanoes are often formed, and the neighbouring ones throw out vast quantities of fire. This was particularly observed in the great earthquake of 1692, when Catania was destroyed, at which fatal moment a vast flame was seen to issue from mount Ætna. But whether any such appearance was observed during the earthquakes of the present year (1783), which seem not to have been less violent than that of 1692, has not yet been authenticated.

16
Incredible
quantities
of electric
matter
emitted by
volcanoes.

We shall only add one remark more in confirmation of the hypothesis that volcanoes are set on fire by electricity, namely, that in a volcanic eruption the quantity of this fluid emitted from the mountain is quite incredible. For a long time together, the smoke is sometimes so much electrified as to attract the ashes which are thrown out along with it almost into a solid column. The stones thrown out, according to Sir William Hamilton, are sometimes transparent, which we can only attribute to an immoderate electricity. Nay, the same author informs us, that the vast stream of lava which issued in 1779 to the height of almost two miles, was transparent also. Add to this, that the volcanic smoke proves very dreadful by reason of the thunder-forms which issue from it. In the great explosion of 1779, which, however, lasted only twenty-five minutes, a cloud of electrified smoke was produced which threatened the destruction of Naples at six miles distance from the mountain; and though it was happily driven from thence by the wind, the air continued so much electrified, that a Leyden vial armed with a pointed wire soon became considerably charged by being only held out at a window. At Ottaviano, which was involved in this cloud, incessant flashes of lightning added greatly to the horror of the

scene, as well as to the danger of the inhabitants. Volcano. By another day's eruption the air was filled with meteors resembling falling stars, which give us a yet higher idea of the quantity of electric matter emitted, as these indicate a greater degree of electricity than even the most violent forked lightning. See LIGHTNING, n° 7.

Thus we have attempted to explain the original cause of volcanoes, the formation of lava, and the reason why the volcanic eruptions are not constant, but only take place at uncertain intervals. It now remains only to assign a reason why volcanoes do not burn quietly as any common fire, but, even during the time of an eruption, by fits and intervals. The explosions indeed are in a manner continued; but, Sir William Hamilton observes, that the burning mountains are subject to what he calls a *crisis at noon and midnight*. The exacerbations also are very remarkable, so that our author distinguishes them by the name of *fever-fits*. All these phenomena, however, may be solved by an attentive consideration of the principles above laid down. The lava is formed by a great quantity of electric matter violently forcing itself through a small spot of earth, in consequence of which that spot is melted, and thus becomes a better conductor of electricity than before, whence the force of the electric blast towards that place is still augmented. Now, as the earth is composed of what we call simply *mould*, together with stones, and minerals of various kinds, moistened with a certain quantity of water, it is not possible that a mass of this kind can be melted without the production of an incredible quantity of steam of various kinds. It is not only the aqueous vapour that is here concerned, but almost all the different kinds we can imagine. No doubt the steam of water alone shows, in certain circumstances, an incredible degree of strength; but of all vapours hitherto known, the aerial ones are the most powerful in their effects as well as the quickest in their operation. Mr Robins, in his Treatise on Gunnery, relates some experiments, from which he concluded, that air, heated to an intense white heat, was expanded into more than four times its usual bulk, and consequently, in such circumstances, has more than four times its usual elasticity. From another experiment he showed, that inflamed gun-powder produces a quantity of permanently elastic steam equivalent to 244 times the bulk of the gun-powder itself. Hence he concludes, that the force of inflamed gun-powder is nearly equal to 1000 times the pressure of the common atmosphere. Now, though the air produced by the inflammation of gun-powder is of a different kind from that which we may suppose to be produced by the melting of a lava, and in much greater quantity in proportion to the bulk of most of the materials, yet it does not appear that the elasticity of the volcanic steam is at all inferior, as far as it goes. From Dr Priestley's experiments it appears, that the expansion of the different kinds of air by heat are in the following proportions:

| | | | | |
|-----------------|---|---|---|-----------|
| Common air | - | - | - | 132 |
| Inflammable | - | - | - | 205 |
| Nitrous | - | - | - | 202 |
| Fixed | - | - | - | 220 |
| Marine acid | - | - | - | 133 |
| Dephlogificated | - | - | - | 221 |
| Phlogificated | - | - | - | 165 |
| | | | | Vitriolic |

17
Explosions
and exacer-
bations of
volcanoes
accounted
for.

| | | |
|----------------|-------|-----|
| Vitriolic acid | - - - | 237 |
| Fluor acid | - - - | 283 |
| Alkaline | - - - | 475 |

In order to form some estimate of the force of volcanic steam, however, it is necessary not only that we should know the different elasticity of the airs which may be supposed to be extricated, but the proportions which are yielded by different substances. But here our data are very slender. Dr Priestley, to whom we must in a manner wholly have recourse, has not made experiments on those substances which we can most reasonably suppose to exist in the bowels of the earth. From some, however, air was discharged in the following proportions, with a heat indeterminate indeed, but certainly not greater than that of a volcano.

| | | |
|-------------------|---|------------------------------|
| Wood-ashes | - | 160 times their own quantity |
| Pitcoal ditto | - | 110 |
| Lapis calaminaris | - | 306 |
| Manganese | - | 40 |
| Chalk | - | 1 |

All these substances we may with good reason suppose to exist in a volcano, or at least substances equally ready to discharge air. Nay, Dr Priestley himself supposes as much dephlogisticated air to be discharged from the melted materials of a lava as is sufficient to continue the burning. But however much he may be in the right with regard to the quantity of dephlogisticated air produced in this manner, he must certainly be mistaken as to the use of it. It is certain that the burning must have commenced before any air could be emitted from the materials, and the cause which produced must also be sufficient to continue it; not to mention that lava could not be kept melted, nor stones red-hot, by blowing air in any quantity upon their surfaces.

With regard to the effects of this steam, we must easily see, that where the quantity of materials is very large, it must be extremely formidable. From the calculations of Dr Priestley above-mentioned, it appears, that fixed air let loose and heated is more powerful than atmospheric air, and consequently more so than even the air emitted by gun-powder, which Mr Robins observes to have much the same elasticity with common air. It is true, that nitre yields pure dephlogisticated air, which is somewhat more elastic than fixed air: but it is instantly phlogisticated by the other ingredients; and Dr Priestley found what remains after the accession of gun-powder to be more phlogisticated than common air, and consequently to have very little more elasticity, as Mr Robins observed. Now, the steam of a volcano must undoubtedly be composed of fixed air, vitriolic acid, some marine acid, dephlogisticated and inflammable air, all blended together at once by the melting of the lava, not to mention a prodigious quantity of aqueous steam rarefied and heated to an extreme degree. As all these are more powerful than an equal quantity of the vapour of inflamed gun-powder, no wonder that such terrible effects ensue from it. From Dr Priestley's calculation, it appears that two ounces of wood-ashes, if a strong white heat could be suddenly applied to them in such a manner as to make them give out all their air at once, would be much more powerful than one ounce of gun-powder; three ounces of pit-coal ashes would be more powerful than an ounce and an half of gun-powder; six ounces of manganic

would be more than an equivalent to one ounce, and 15 pounds of chalk would be the same; though this last we may be assured would in such circumstances yield more than 50 times the quantity of air that Dr Priestley could obtain from it. Lapis calaminaris would be terrible beyond all measure; one ounce of it being nearly equivalent to two of gun-powder. What must be the consequence, then, if thousands of tons of materials equally prolific in such kinds of air are melted at once?

When all this is attentively considered, we will be so far from being surpris'd at the immense power of volcanoes, that it will rather be matter of surpris'e that more mischief is not done by them than what actually happens. This however is prevented by the force being constantly directed upwards, and not horizontally along the surface of the earth. The first consequence of the production of a lava must be a violent tendency of it to expand. The reason of this is obvious, viz. because the steam is dispersed through every part of it, and therefore swells and heaves it up, as we see is the case with any glutinous fluid when set over the fire to boil. As this expansion is very violently resisted by the obstacles below ground, the overcoming of these, which in fact is no less than removing and breaking to pieces rocks and huge masses of earth, must be attended with the most tremendous explosions; and hence we may account for the noises below ground before an eruption of a volcano takes place. As the lava is excessively tenacious, it will continue to swell, and keep the steam within itself for a long time, though violent blasts of smoke and elastic steam will now and then get out, as we see that puffs of smoke will get out from any thick matter boiling over a fire. As these blasts of volcanic steam must also be composed partly of the smoke of burnt earth, and partly of elastic air, they are consequently of a black colour; and hence the sign of an approaching eruption is a quantity of black smoke now and then shooting up to an immense height in the air. Along with this black smoke, however, a white one will be emitted without intermission. This white smoke is composed of aqueous vapour, and what comes from the outside of the lava when thoroughly melted, which is always observed to emit a white steam. As the lava advances, a prodigious quantity of earth, stones, &c. are collected on its upper part, so that the blasts of steam cannot get out without breaking through this covering. The earth in the mean time is calcined to ashes, and the stones are made red-hot by the vehement heat of the lava underneath, and by the violent current of electric matter converging towards that point. The volcano therefore begins to throw up red-hot stones, cinders, ashes, and scorize of the lava itself. These falling down into the crater, continually fill it up; and thus confining the steam, give constant occasion for fresh explosions, and the mountain continues to rage with more or less violence, according to the quantity of steam yielded by the lava, and the degree of resistance it meets with. At last, when the lava has reached the summit, or meets with a weak place in the mountain, as the same tendency to expand still continues, it runs over the top, or bursts out thro' the side. Then all the violent explosions and fury of the volcano cease, because the steam gets continual vent by forcing more of the lava out through the opening. But if by any accident the running

Volcano. The eruption of the lava happens to be stopped, or the vent happens to be too narrow, all the former phenomena return, sometimes with double violence.

Thus we may in a pretty plausible manner account for the general phenomena of volcanoes; and if extraordinary phenomena sometimes occur, we may reasonably suppose them to be owing to some accidental circumstance. Thus the vast height to which the lava of Vesuvius ascended in 1779, must certainly have been occasioned by some extraordinary pressure, such as indeed we may well be surpris'd how the sides of the mountain could bear. There are three circumstances which may reasonably be supposed to cause the lava spring up to a considerable height. 1. Its being very suddenly formed; for thus all the elastic steam will be discharged in a manner at once, and the tendency to expand will be inconceivably great. 2. The degree of resistance. And, 3. The capability of the materials to produce elastic steam. All these seem to have concurred to produce the great explosion on the 8th of August 1779. The immense quantity of electric fluid which at this time issued from the mountain, indicated that the lava had been suddenly formed. Immediately before its emission, such a report was heard as shook the houses at Portici, broke the windows, and cracked several walls; and the fitness of the materials at that time in the mountain for producing elastic steam, appeared from the vast quantities of smoke which issued along with the lava.

With regard to the uses of volcanoes, we may observe, that however terrible their eruptions may be, they answer very important purposes in nature, by giving vent to such quantities of electric matter as might otherwise render the earth totally uninhabitable, if not endanger its frame altogether. Sulphur, sal ammoniac, and various other salts, are produced by them; their ashes fertilize the neighbouring country; and the lavas, tuffs, basaltas, &c. afford materials for building. By their means also many islands have been thrown up from the bottom of the sea, and afford new habitations for man.

VOLERY, a great bird-cage, so large that the birds have room to fly up and down in it.

VOLITION, the act of willing. See **METAPHYSICS**.

VOLLEY, a military salute, made by discharging a great number of fire arms at the same time.

VOLONES, in Roman antiquity, slaves who in the Ponic war voluntarily offered their service to the state; which is the reason of the appellation; upon which they were admitted to citizenship, as none but freemen could be soldiers.

VOLT, in the manage, a round or circular tread; and hence, by the phrase *to make volts*, is understood a gate of two treads, made by a horse going sidewise round a centre, in such a manner that these two treads make parallel tracts; one larger, made by the fore feet, and another smaller made by the hind-feet; the croup approaching towards the centre, and the shoulders bearing out.

VOLTAIRE (Francis de), one of the most celebrated French authors and wits, was born in the year 1694. At twelve years of age, having written some verses that appeared to be superior to what could have been expected at that early period, he was introduced to

the celebrated Ninon d'Enclos by the Abbe Chateaufort, her intimate friend; and that extraordinary woman bequeathed to him the sum of 2000 livres to buy books; which legacy was punctually paid.

Notwithstanding his extreme youth, he was admitted to an intimacy with the Abbe Chaulien, the Marquis de la Fare, the duke of Sully, and the Abbe Courtin; and he has often told us that his father believed him entirely ruined, because he kept company with people of fashion and made verses.

At the age of 18, he began the tragedy of Oedipus, in which he proposed to introduce choruses after the manner of the ancients. The players were very unwilling to appear in a tragedy, the subject of which had been already treated by Corneille, whose performance was what is commonly called a *stock play*. It was not acted till 1718, and even then not without an order from the court. The young man, who was excessively dissipated, and immersed in all the pleasures common at his time of life, was not sensible of the risk he ran, nor did he give himself any trouble whether his pieces succeeded or not. He indulged himself in a thousand sallies on the stage; and at last wantonly laid hold of the train of the chief priest, in a scene where that pontiff was producing a very tragical effect. Marechal Villars's lady, who was in the first box, inquired who the young man was that had played that trick, as it seemed to be done with a view to ruin the piece; and being told that he was the author, she sent for him into the box, and the attachment he formed from that time to the marechal and his lady continued during their lives.

After having finished his Oedipus, but before it had been performed, he began the Henriade; when, with Monsieur de Caumartin, intendant of the finances at St Ange, having one day read several cantos of his poem when on a visit to his intimate friend the young president de Maisons, he was so teized with objections, that he lost patience, and threw his manuscript into the fire. The president Henaut with difficulty rescued it. "Remember (said M. Henaut to him, in one of his letters), it was I that saved the Henriade, and that it cost me a handsome pair of ruffles." Some years after, several copies of this poem were handed about while it was only a sketch; and an edition of it with many changes was published under the title of *The League*. All the poets in Paris, and even many of the learned, fell foul of him. The Henriade was played at the fair; and it was insinuated to the old bishop of Frejus, preceptor to the king, that it was indecent, and even criminal, to write in praise of admiral Coligny and queen Elizabeth. The cabal had interest enough to engage cardinal de Bissy, then president of the assembly of the clergy, to pass a judicial censure upon the work; but this strange design proved abortive. The young author was filled with equal surprise and resentment at these intrigues. His dissipation prevented him from making friends among the literati; and he had not the art of combating his enemies with their own weapons, which is said to be absolutely necessary in Paris, if a man wishes to succeed in any kind of pursuit.

In 1722, he gave the tragedy of Mariamne. That princess was poisoned by Herod. When she drank the cup, the faction cried out, "The queen drinks;" and the piece was damned. These continual mortifications deter-

Voltaire. determined him to print the *Henriade* in England, as he could neither obtain privilege nor patronage for it in France.

Here king Geo. I. and more particularly the prince of Wales, afterwards queen of England, raised an immense subscription for him. Their liberality laid the foundation of his fortune: for on his return to France in 1728, he put his money into a lottery established by Mr Desforts, comptroller general of the finances. The adventurers received a rent-charge on the *Hôtel-de-Ville* for their tickets; and the prizes were paid in ready money: so that if a society had taken all the tickets, it would have gained 1,000,000 of livres. He joined with a numerous company of adventurers, and was fortunate.

We are afterwards informed of the bad success of his *Brutus* and *Zara*; and of the refusal of the academicians to admit him into their society. About this time he became intimately acquainted with the illustrious marchioness of Chateliet, with whom he studied the principles of Newton, and the systems of Leibnitz. They retired to Cirey, in Champagne, for several years; two of which Mr Kœnig, an eminent mathematician, passed with them. Mr Voltaire caused a gallery to be erected, where they performed all the experiments on light and electricity. When he attempted to publish his *Elements of the Newtonian Philosophy*, a philosophy then scarce known in France, he could not obtain a privilege from the chancellor Aguessau, who was a man of universal learning, but being bred a Cartesian, discouraged the new discoveries as much as he could. Our author's attachment to the principles of Newton and Locke, drew upon him a new crowd of enemies. He wrote to Mr Falkner, to whom he dedicated his *Zara*. "It is believed that the French love novelty, but it must be in cookery and fashions, for as to new truths they are always proscribed among us; it is only when they grow old that they are well received."

By way of relaxation from his studies in natural philosophy, he amused himself in writing his *Maid of Orleans*. Although this poem was only comic, yet there is much more fancy in it than in the *Henriade*; but it was vilely disgraced by some shameless scoundrels, who printed it with horrid lewdnesses. The only good editions are those of Geneva. Not long afterwards, he became acquainted with the celebrated Rousseau at Brussels; and they soon conceived a strong aversion for each other. Rousseau having shown his antagonist a lyric epistle addressed to posterity, met with this reply: "My friend, this letter will never be delivered according to its direction." Rousseau never forgave this piece of rillery.

In the year 1738, he commenced a correspondence with the king, then hereditary prince-royal, of Prussia; and in the year 1740 he went to pay his court at Berlin before the king was prepared for invading Silesia. Soon after his return from Berlin, he wrote the tragedies of *Mahomet* and *Merope*. The tragedy of *Merope* is the first piece, not upon a sacred subject, that succeeded without the aid of an amorous passion, and which procured our author more honour than he hoped from it. It was played on the 26th of February 1743.

Soon after, we see him again taking a journey to the king of Prussia, who was always inviting him to Berlin, but could never prevail on him to quit his old

friends for any considerable time. In his journey he performed a singular service to the king his master; as we see by the letters which passed between him and Mr Amelot the minister of state.

In the year 1749, after the death of the illustrious marchioness of Chateliet, whom Mr Voltaire had attended to the court of Stanislaus, the king of Prussia gave him an invitation to come and live with him. It was not till towards the end of the month of August 1750, after having for six months combated the opinions of all his friends, who strongly dissuaded him from going, that we find him resolved to quit France, and attach himself to his Prussian majesty for the rest of his life. He could not withhold the letter which the king of Prussia wrote to him on the 23d of August from the apartments destined for his future guest in the palace of Berlin: a letter which has been often printed, and is universally known.

After this letter, the king of Prussia asked the consent of the king of France, by his minister at that court, which was readily granted. Our author was presented at Berlin with the order of Merit, the key of chamberlain, and a pension of 20,000 livres. However, he did not give up his house at Paris; and by the account of Mr Delaieu the notary, we find that Mr Voltaire was at the expense of 30,000 livres a-year there. He was attached to the king of Prussia by the most respectful regard, as well as by their conformity of taste. He has a hundred times said, that monarch was as agreeable in company as he was formidable at the head of an army; and that he had never more pleasing evening parties at Paris, than those to which that prince would have constantly admitted him. His regard for the king of Prussia rose to a degree of enthusiasm. His apartments were under the king's, and he never quitted them but to go to supper. The king composed works in philosophy, history, and poetry, in the upper apartments, while his favourite cultivated the same arts and the same talents in the lower. They communicated their works to one another. The Prussian monarch wrote his *Memoirs of the House of Brandenburg at Potsdam*; and the French author having carried his materials with him, wrote his *Age of Lewis XIV.* at the same place. Thus did his days glide along in tranquillity, enlivened by such agreeable employments.

This happiness would have been more lasting, if it had not been for a dispute on a subject in mixed mathematics which arose between Maupertuis, who likewise lived at that time with the king of Prussia, and Kœnig librarian to the prince of Orange at the Hague. This dispute was a continuation of that which for a long time had divided the mathematicians about the living and dead forces. The tempers of the disputants were soured; and Maupertuis, who ruled the academy at Berlin, procured a condemnation of Kœnig's opinion in the year 1752, on the authority of a letter of the late Leibnitz, without being able to produce the original of that letter, which however had been seen by Mr Wolf. He went still farther.—He wrote to the prince of Orange, to beg her to dismiss Kœnig from his employment of librarian; and represented him to the king of Prussia as a man who had been wanting in the respect due to his Majesty. Voltaire, who had passed two whole years at Cirey with Kœnig,

Voltaire
||
Volute.

Kœnig, during which he had contracted an intimacy, thought it was his duty openly to espouse the cause of his friend. The quarrel became violent; and Maupertuis having reported that Voltaire had spoken disrespectfully of the king's literary abilities, the latter returned the key of chamberlain, &c. which, however, the king sent him back.

Soon after his departure from Berlin, he purchased the seignory of Ferney in the *pays de Gex*, about a league from Geneva. It was here that he undertook the defence of the celebrated family of Calas; and it was not long before he had a second opportunity of vindicating the innocence of another condemned family of the name of *Sirven*. It is somewhat remarkable, that in the year 1774, he had the third time a singular opportunity of employing that same zeal which he had the good fortune to display in the fatal catastrophe of the families of Calas and Sirven.

In this retreat M. Voltaire continued long to enjoy the pleasures of a rural life, accompanied with the admiration of a vast number of wits and philosophers throughout all Europe. Worn out at length, however, with his situation, or yielding to the importunities of friends, he came to Paris about the beginning of the year 1778, where he wrote a new tragedy called *Irene*. By this time his understanding seems to have been impaired, either through the infirmities of age, or continued intoxication by the flattery of others; and he ridiculously suffered himself to be crowned in public with laurel, in testimony of his great poetical merit. He did not long survive this farce: for having over-heated himself with receiving visits, and exhausted his spirits by supplying a perpetual fund of conversation, he was first seized with a spitting of blood; and at last becoming restless in the night-time, he was obliged to use a soporific medicine. Of this he unluckily one night took too large a dose, that he slept 36 hours, and expired a very short time after awaking from it.

VOLUME, in matters of literature, a book or writing of a just bulk to be bound by itself. The name is derived from the Latin *volvere*, "to roll up;" the ancient manner of making up books being in rolls of bark or parchment. See **BOOK**.

VOLUNTARY, in music, a piece played by a musician extempore, according to his fancy. This is often used before he begins to set himself to play any particular composition, to try the instrument, and to lead him into the key of the piece he intends to perform.

VOLUNTEERS, persons who, of their own accord, either for the service of their prince, or out of the esteem they have for their general, serve in the army without being enlisted, to gain honour and preferment, by exposing themselves in the service.

VOLVOX, in natural history, a genus of insects belonging to the order of vermes zoophyta. The body is round, gelatinous and destitute of limbs. For an account of the beroc, a species of this genus, see the article **ANIMALCULA**, n° 46.

VOLUTA, in natural history, a genus of insects belonging to the order of vermes. The animal is of the snail kind, with an unilobular spiral shell, of which there are 46 species, distinguished by peculiarities in their shells.

VOLUTE, in architecture, a kind of spiral scroll
Vol. X.

Vomica
||
Vossius.

used in the Ionic and Composite capitals, whereof it makes the principal characteristic and ornament.

VOMICA, is commonly taken for a suppurated imposthume, or an abscess with a suppuration. See **MEDICINE**, n° 535.

NUX VOMICA, in pharmacy, a flat compressed round fruit, of the breadth of a shilling, or somewhat more, and of about the thickness of a crown piece.

It is the nucleus of a fruit of an East-Indian tree, the wood of which is the *lignum colubrinum* of the shops.

Some have prescribed small doses of the *nux vomica* as a specific against a gonorrhœa, and others against quartan agues. But we have so many good and safe medicines for all these purposes, that there seems no occasion for our having recourse to such as these, which show so many signs of mischief.

VOMIT. See **EMETIC**.

VOMITING, a retrograde spasmodic motion of the muscular fibres of the œsophagus, stomach, and intestines, attended with strong convulsions of the muscles of the abdomen and diaphragm, which, when gentle, create a nausea; when violent, a vomiting.

VOORN, one of the islands of Holland, bounded by the river Maas, which divides it from the continent and the island of IJsemond, on the north; by the sea called the *Biesbosch*, on the east; by another branch of the Maas, which divides it from the islands of Goree and Overflackee, on the south; and by the German sea on the west; being about 24 miles long, and 5 broad.

VORTEX, in meteorology, a whirlwind, or sudden, rapid, and violent motion of the air in gyres, or circles.

Vortex is also used for an eddy or whirlpool; or a body of water, in certain seas or rivers, which run rapidly around, forming a sort of cavity in the middle.

VORTEX, in the Cartesian philosophy, is a system or collection of particles of matter moving the same way, and round the same axis.

Such vortices are the grand machines whereby those philosophers solve most of the motions and other phenomena of the heavenly bodies. Accordingly, the doctrine of these vortices make a great part of the Cartesian philosophy.

VOSSIUS (John Gerard), one of the most learned and laborious writers of the 17th century, was of a considerable family in the Netherlands; and was born in 1577, in the Palatinate, near Heidelberg, at a place where his father, John Vossius, was minister. He became well skilled in polite literature, history, and sacred and profane antiquities, and was made director of the college of Dort. He was at length made professor of eloquence and chronology at Leyden, from whence he was called in 1633 to Amsterdam, to fill the chair of a professor of history. He died in 1649. He wrote many learned works, of which a complete edition has been printed at Amsterdam, in 9 vols folio.

Vossius (Isaac), a man of great parts and learning, the son of John Gerard Vossius, was born at Leyden in 1618. He had no other tutor but his father, and employed his whole life in studying: his merit recommended him to a correspondence with queen Christina of Sweden; he made several journeys into Swe-

Vote
Upfal.

den by her order, and had the honour to teach her the Greek language. In 1670 he came over to England, where king Charles made him canon of Windsor; tho' he knew his character well enough to say, That there was nothing that Vossius refused to believe, excepting the Bible. He appears indeed by his publications, which are neither so useful nor so numerous as his father's, to have been a most credulous man, while he afforded many circumstances to bring his religious faith in question. He died at Windsor castle in 1688.

VOIE, the suffrage or resolve of each of the members of an assembly, where any affair is to be carried by a majority; but more particularly used for the resolves of the members of either house of parliament.

VOTIVE MEDALS, those on which are expressed the vows of the people for the emperors or empresses. See MEDAL.

VOW, a solemn and religious promise, or oath. See OATH.

The use of vows is found in most religions. They make up a considerable part of the Pagan worship, being made either in consequence of some deliverance, under some pressing necessity, or for the success of some enterprise. Among the Jews, all vows were to be voluntary, and made by persons wholly in their own power; and if such person made a vow in any thing lawful and possible, he was obliged to fulfil it. If he appointed no particular time for accomplishing his vow, he was bound to do it instantly, lest by delay he should prove less able, or be unwilling, to execute his promise. Among the Romanists, a person is constituted a religious by taking three vows; that of poverty, chastity, and obedience.

Vows, among the Romans, signified sacrifices, offerings, presents, and prayers made for the Cæsars and emperors, particularly for their prosperity and the continuance of their empire. These were at first made every 5 years, then every 15, and afterwards every 20, and were called *quinquennialia*, *decennialia*, and *vincennialia*.

VOWEL, in grammar, a letter which affords a complete sound of itself, or a letter so simple as only to need a bare opening of the mouth to make it heard, and to form a distinct voice.

The vowels are six in number, *viz.* A, E, I, O, U, Y, and are called *vowels*, in contradistinction to certain other letters, which, depending on a particular application of some part of the mouth, as the teeth, lips, or palate, can make no perfect sound without an opening of the mouth, that is, without the addition of a vowel, and are therefore called *consonants*.

VOWEL (John). See HOOKER.

UPHOLSTER, UPHOLSTERER, or Upholder, a tradesman that makes beds, and all sorts of furniture therunto belonging, &c.

UPLAND, denotes high ground, or, as some call it, *terra firma*, by which it stands opposed to such as is moorish, marshy, or low.

UPLAND, a province of Sweden, bounded on the north-east by the Baltic Sea, on the south by the sea of Sudermania, and on the west by Westmania and Gestricia, from which it is separated by the river Dela. It is about 70 miles in length and 45 in breadth, and contains mines of iron and lead. Stockholm is the capital.

UPSAL, a rich and considerable city of Sweden, in

Upland, with a famous university, and an archbishop's see. The town is pretty large, and as straight as a line; but most of the houses are of wood, covered with birch-bark, with turf on the top. On an eminence, to the south of the town, is a ruined castle. Those that view the town from hence would take it to be a garden, whose streets represent the alleys; and the houses, which are covered with turf, the grass-plats. It was formerly the residence of the kings, and is now the usual place where they are crowned. It is seated on the river Sala, over which there are two bridges. It is 27 miles north-west of Stockholm. E. Lon. 17. 56. N. Lat. 60. 10.

UPUPA, in ornithology, a genus belonging to the order of picæ. The beak is arcuated, convex, and something blunt; the tongue is obtuse, triangular, entire, and very short; and the feet are fitted for walking. There are two species; both natives of India. The epops, hoopoe, or dung-bird, is frequently seen in Britain. It may be readily distinguished from all others that visit these islands by its beautiful crest, which it can erect or depress at pleasure. It is in length 12 inches; in breadth, 19; the bill is black, two inches and a half long, slender, and incurved; the irides are hazel; the crest consists of a double row of feathers; the highest about two inches long; the tips are black; their lower part of a pale orange colour; the neck is of a pale reddish brown; the breast and belly white; the lesser coverts of the wings are of a light brown; the back, scapulars, and wings, crossed with broad bars of white and black; the rump is white; the tail consists of only 10 feathers, white marked with black, in form of a crescent, the horns pointing towards the end of the feathers. The legs are short and black; the exterior toe is closely united at the bottom to the middle toe.

According to Linnæus, it takes its name from its note, which has a sound similar to the word; or it may be derived from the French *huppe*, or "crested;" it breeds in hollow trees, and lays two ash-coured eggs; it feeds on insects, which it picks out of ordure of all kinds: the ancients believed that it made its nest of human excrement; so far is certain, that its hole is excessively fetid from the tainted food it brings to its young. The country people in Sweden look on the appearance of this bird as a presage of war;

Fucies armata videtur.

And formerly the vulgar in our own country esteemed it a forerunner of some calamity. It visits these islands frequently; but not at stated seasons, neither does it breed with us. It is found in many parts of Europe, in Egypt, and even as remote as Ceylon. The Turks call it *tir chaos*, or the "messenger-bird," from the resemblance its crest has to the plumes worn by the chaos or Turkish couriers.

Ovid says that Tereus was changed into this bird:

*Veritur in volucem, cui stant in vertice crisse,
Prominet immodicum pro longa cuspidæ refruant
Nomen epops volucris.* Metam. lib. vi. l. 671.

Tereus, through grief and haste to be reveng'd,
Shares the like fate, and to a bird is chang'd.
Fix'd on his head the crested plumes appear.
Long is his beak, and sharpen'd as a spear.

Croall.

UR (anc. geog.), a citadel of Mesopotamia, situate between the Tigris and Nisibis; taken by some for Ur of

Upupa,
Ur.

Uranburg
Urim.

of the Chaldees, the residence of Abraham. What seems to confirm this is, that from Ur to Haran, the other residence of the patriarch, the road lies directly for Palestine. And it is no objection that Ur is said to be in Mesopotamia; because the parts next the Tigris were occupied by the Chaldeans, as seems to be confirmed from A&S vii. 2, 4. It is called *Orche*, in Strabo; *Orchoe*, in Ptolemy.

URANBURG, or URANIBURG, a castle of Denmark, situated on the little island of Huen, in the Sound, 16 miles north-east of Copenhagen. Here was the celebrated observatory built by that noble Dane Tycho Brahe, and furnished with instruments for observing the course and motions of the heavenly bodies.

URANIA, in fabulous history, one of the nine Muses, was supposed to preside over astronomy. She is commonly represented in an azure robe, crowned with stars, and supporting a large globe with both hands.

URANOSCOPUS, in ichthyology, a genus belonging to the order of jugulares. The head is large, rough, and depressed, the upper jaw being shorter than the under one; there are five dentated rays in the membrane of the gills; and the anus is in the middle of the body. There is but one species, found in the Mediterranean sea.

URBINO, a province of Italy, in the pope's territory, bounded by Romania and the gulph of Venice on the north and east, by the marquise of Ancona on the south, and by Tuscany on the west, being 70 miles long, and from 20 to 50 broad.

Urbino is also the capital of this province.

URCHIN, in zoology. See ECHINUS.

URETERS, in anatomy. See ANATOMY, n° 363.

f. URETHRA, in anatomy. See ANATOMY, n° 371.

URIM and THUMMIM, among the ancient Hebrews, a certain oracular manner of consulting God, which was done by the high-priest dressed in his robes, and having on his pectoral or breast-plate.

Various have been the sentiments of commentators concerning the urim and thummim. Josephus, and several others, maintain, that it meant the precious stones set in the high-priest's breast-plate, which by extraordinary lustre made known the will of God to those who consulted him. Spencer believes that the urim and thummim were two little golden figures shut up in the pectoral as in a purse, which gave responses with an articulate voice. In short, there are as many opinions concerning the urim and thummim as there are particular authors that wrote about them. The safest opinion, according to Broughton, seems to be, that the words *urim* and *thummim* signify some divine virtue and power annexed to the breast-plate of the high-priest, by which an oracular answer was obtained from God when he was consulted by the high-priest; and that this was called *urim* and *thummim*, to express the clearness and perfection which these oracular answers always carried with them; for *urim* signifies "light," and *thummim* "perfection;" these answers not being imperfect and ambiguous, like the heathen oracles, but clear and evident. The use made of the urim and thummim was to consult God in difficult cases relating to the whole state of Israel; and sometimes in cases relating to the king, the sanhe-

drim, the general of the army, or some other great personage.

URINAL, in medicine, a vessel fit to receive and hold urine, and used accordingly for the convenience of sick persons. It is usually of glass, and crooked; and sometimes it is filled with milk, to assuage the pain of the gravel.

URINAL, in chemistry, is an oblong glass vessel, closed for making solutions, and so called from its resemblance to the glasses in which urine is set to settle for the inspection of the physician.

URINE, a serous and saline fluid, of a citron colour, separated from the blood, and carried by the emulgent arteries to the kidneys, from whence it descends to the bladder by the ureters, and is from time to time emitted thence by the canal of the urethra. See ANATOMY, n° 365. For the analysis of urine, see CHEMISTRY, n° 308.

URN, a kind of vase, of a roundish form, but biggest in the middle, like the common pitchers, now seldom used but in the way of ornament over chimney-pieces, in buffets, &c. The great use of urns among the ancients, was to preserve the ashes of the dead after they were burnt; for which reason they were called *cineraria*, and *urna cineraria*, and were placed sometimes under the tomb-stone whereon the epitaph was cut; and sometimes in vaults in their own houses. Urns were also used at their sacrifices to put liquid things in.

UROGALLUS, in ornithology. See TETRAO.

URSA, in astronomy. See ASTRONOMY, n° 206.

URSULINES, in church-history, an order of nuns, founded originally by St Angela of Brescia, in the year 1537; and so called from St Ursula, to whom they were dedicated. They observe the rules of St Augustine, and are chiefly noted for taking on them the education and instruction of young maids: their monasteries are a kind of schools where young ladies of the best families receive their education.

URSUS, the BEAR; a genus of quadrupeds belonging to the order of feræ. There are six fore-teeth in the upper jaw, alternately hollow in the inside, and six in the under jaw, the two lateral ones being labiated. The dog-teeth are solitary and conical; the eyes are furnished with a nictitating membrane; the nose is prominent; and there is a crooked bone in the penis. There are five species, viz.

1. The *ursus cauda abrupta*, has strong, thick, and clumsy limbs; very short tail; large feet; body covered with very long and shaggy hair, various in its colour: It inhabits the north parts of Europe and Asia; the Alps of Switzerland, and Dauphine; Japan and Ceylon; North America and Peru. The brown bears are sometimes carnivorous, and will destroy cattle, and eat carrion; but their general food is roots, fruits, and vegetables: they will rob the fields of pease; and when they are ripe, pluck great quantities up, beat the pease out of the husks on some hard place, eat them, and carry off the straw: they will also, during winter, break into the farmer's yard, and make great havoc among his stock of oats; they are also particularly fond of honey. The bears of America are small and black, and confine themselves entirely to vegetables: they are remarkably greedy of maize and potatoes; and will even reject animal-food, though pressed by hunger: neither of these varieties

Urnal
Uris.

will attack mankind, unless wounded, or when they have their young: they strike with their fore-feet like a cat; seldom or never use their mouths in fighting, but seizing the assailant with their paws, and pressing him against their breast, almost instantly squeeze him to death. The females after conception retire into the most secret places; left, when they bring forth, the males should devour the young: it is affirmed, that out of the several hundred bears that are killed in America, during winter, (which is their breeding season), scarce a female is found among them; so impenetrable is their retreat during their pregnancy: they bring two, rarely three, young at a time: the cubs are deformed, but not a shapeless mass to be licked into shape, as the ancients pretended. The flesh of a bear in autumn, when they are excessively fat, by feeding on acorns, and other mast, is delicate food; and that of the cubs still finer; but the paws of the old bears are reckoned the most exquisite morsel; the fat white, and very sweet; the oil excellent for strains and old pains. The latter end of autumn, after they have fattened themselves to the greatest degree, the bears withdraw to their dens, where they continue for a great number of days in total inactivity, and abstinence from food, having no other nourishment than what they get by sucking their feet, where the fat lodges in great abundance; their retreats are either in cliffs of rocks, in the deepest recesses of the thickest woods, or in the hollows of ancient trees, which they ascend and descend with surprising agility: as they lay in no winter-provisions, they are in a certain space of time forced from their retreats by hunger, and come out extremely lean: multitudes are killed annually in America, for the sake of their flesh or skins; which last makes a considerable article of commerce.

2. The polar, or white bear, has a long head and neck; short round ears; great teeth; the hair long, soft, and white, tinged in some parts with yellow: growing to a vast size; the skins of some being 13 feet long.

This animal is confined to the coldest part of the globe; it has been found as far as navigators have penetrated northwards, above lat. 80. The frigid climes only seem adapted to its nature; for we do not learn from any authority that it is met with farther south than Newfoundland. Its bounds in respect to longitude are also very limited; being an animal unknown except on the shores of Hudson's Bay, Greenland, and Spitzbergen, on one side, and those of Nova Zembla on the other; for such as have appeared in other parts have been brought there involuntarily on floating islands of ice; so that the intermediate countries of Norway and Iceland are acquainted with them but by accident. We cannot trace them farther east than Nova Zembla; though the frozen sea, that is continued from thence as far as the land of Tschuktschi, that lies above Kamtschatka, is equally suited to their nature. The late histories of those countries are silent in respect to them.

During summer, the white bears are either resident on islands of ice, or passing from one to another: they swim admirably, and can continue that exercise six or seven leagues, and dive with great agility. They bring two young at a time: the affection between the parents and them is so strong, that they would die rather than desert one another. Their winter retreats are under the

snow, in which they form deep dens, supported by pillars of the same. They feed on fish, seals, and the carcases of whales, and on human bodies, which they will greedily tear up: they seem very fond of human blood; and are so fearless as to attack companies of armed men, and even to board small vessels. When on land, they live on birds and their eggs; and allured by the scent of seals fish, often break into and plunder the houses of the Greenlanders: their greatest enemy in the brute creation is the morse, with whom they have terrible conflicts, but are generally worsted, the vast teeth of the former giving it a superiority. The flesh is white, and said to taste like mutton: the fat is melted for train-oil, and that of the feet used in medicine: but the liver is very unwholesome, as three of Barentz's sailors experienced, who fell dangerously ill on eating some of it boiled. One of this species was brought over to England a few years ago; it was very furious, almost always in motion, roared loud, and seemed very uneasy, except when cooled by having pailfuls of water poured on it.

3. The luscus, or wolverene, has a black sharp pointed visage; short rounded ears, almost hid in the hairs; the sides of a yellowish brown, which passes in form of a band quite over the hind-part of the back, above the tail; the legs are very strong, thick and short, of a deep black: the whole body is covered with very long and thick hair, which varies in colour according to the season. It inhabits Hudson's Bay and Canada, as far as the straits of Michilimackinac; is found under the name of the *glutton* in the north parts of Europe and Asia, being a native of the most rigorous climates.

It is a most voracious animal, and slow of foot; so is obliged to take its prey by surprise. In America it is called the *beaver-eater*, watching those animals as they come out of their houses, and sometimes breaks into their habitations, and devours them. It often lurks on trees, and falls on the quadrupeds that pass under; will fasten on the horse, elk, or stag, and continue eating a hole into its body, till the animal falls down with the pain; or else will tear out its eyes: no force can disengage it; yet sometimes the deer in their agony have been known to destroy it, by running their head violently against a tree. It devours the otter, or white fox; searches for the traps laid for the fables and other animals; and is often beforehand with the huntsmen, who sustain great losses by the *glutton*: authors have pretended that it feeds so voraciously, that at length it is in danger of bursting; and that it is obliged to ease itself of its load, by squeezing it out between two trees.

In a wild state, it is vastly fierce; a terror to both wolf and bear, which will not prey on it when they find it dead, perhaps on account of its being so very fetid, smelling like a pole-cat: it makes a strong resistance when attacked; will tear the flock from the gun, and pull the traps it is caught in to pieces. Notwithstanding this, it is capable of being tamed, and of learning several tricks; burrows, and has its den under ground. The skin is sold in Siberia for 4s. or 6s.; at Jakutsk for 12s.; and still dearer at Kamtschatka, where the women dress their hair with its white paws, which they esteem a great ornament. The fur is greatly esteemed in Europe: that of the north of Europe and Asia, whose skins are sometimes to be seen in the furriers shops, is much finer, blacker, and more glossy

than that of the wolverene, or American kind. The glutton has by some authors been confounded with the hyæna.

4. The lotor, or raccoon, has the upper part of the body covered with hair, ash-coloured at the root, whitish in the middle, and tipped with black; tail very bushy, annulated with black; toes black, and quite divided.—It inhabits the warm and temperate parts of America; is found also in the mountains of Jamaica, and in the isles of Maria, between the fourth point of California and Cape Corientes, in the South Sea: is easily made tame, very good-natured and sportive; bus as unlucky as a monkey. It is almost always in motion; and very inquisitive, examining every thing with its paws. It makes use of them as hands; sits up to eat; is extremely fond of sweet things, and strong liquors, and will get excessively drunk. It has all the cunning of a fox; and is very destructive to poultry; but will eat all sorts of fruits, green corn, &c. At low water it feeds much on oysters, and will watch their opening, and with its paw snatch out the fish; it sometimes is caught in the shell, and kept there till drowned by the coming in of the tide: it is also fond of crabs. It climbs very nimbly up trees. It is hunted for its skin; the fur next to that of the beaver for making hats.

5. The meles, or common badger, is an animal of a very clumsy make, with short thick legs, long claws on the fore-feet, and a fetid white matter exuding from the orifice below the tail. It inhabits moist parts of Europe, as far north as Norway and Russia, and the step or desert beyond Orenburgh, in the Russian Asiatic dominions, north of the Caspian Sea: inhabits also China, and is often found in the butchers shops in Peking, the Chinese being fond of them; but a scarce animal in moist countries. It seldom appears in the day; confines itself much to its hole: is indolent and sleepy; generally very fat: feeds by night; eats roots, fruits, grubs, insects, and frogs; but is not carnivorous: it runs slowly; when overtaken, it comes to bay, and defends itself vigorously; its bite is dangerous. It burrows under ground; makes several apartments, but forms only one entrance from the surface. It is hunted during night for the skin, which serves for pistol-furniture; the hairs for making brushes to soften the shades in painting. Its flesh makes good bacon.

URTICA, the NETTLE; a genus of the tetrandria order, belonging to the monocœia class of plants.

1. The uren, or lesser stinging nettle, grows in waste places, on dunghills, &c. The stings or prickles of this are very numerous and inflammatory; the leaves of a roundish oval figure, and light green colour: the male and female flowers grow in different parts of the same plant, in crowded oblong green clusters, erect, nearly sessile in the axils of the leaves. The stings are very curious microscopic objects: they consist of an exceedingly fine pointed tapering hollow substance, with a perforation at the point, and a bag at the base. When the spring is pressed upon, it readily perforates the skin, and at the same time forces up some of the acrimonious liquor contained in the bag into the wound.

2. The dioica, or common stinging nettle, grows plentifully in waste places, and under hedges. The male and female flowers grow on distinct plants; the clusters branched, and generally in pairs. The aculei,

or stings of the nettle, have a small bladder at their base, full of a burning corrosive liquor: when touched, they excite a blister, attended with a violent itching pain, though the sting does not appear to be tubular, or perforated at the top, nor any visible liquor to be infused into the puncture made by it in the flesh. It seems certain, however, that some of this liquor is insinuated into the wound, though invisibly, since the stings of the dried plant excite no pain. The chives afford a very pleasing appearance: they are rolled inwards under the segments of the cups, which fold over them till they are ripe, when the segments gradually expanding, the chives released from their confinement, roll back with an elastic force, and discharge the contents of their transparent tips which float in the air like a cloud of dust, that it may arise to the summits of the fertile flowers.

Nettle-tops in the spring are often boiled and eaten by the common people instead of cabbage-greens.

In Arran, and other islands, a rennet is made of a strong decoction of nettles: a quart of salt is put to three pints of the decoction, and bottled up for use. A common spoonful of this liquor will coagulate a large bowl of milk very readily and agreeably. The stalks of nettles are so like in quality to hemp, that in some parts of Europe and Siberia they have been manufactured into cloth, and paper has been made of them. The whole plant, particularly the root, is esteemed to be diuretic, and has been recommended in the jaundice and nephritic complaints. It is also reckoned astringent; and of service in all kinds of hæmorrhagies, but is at present but little in practice. The roots boiled will dye yarn of a yellow colour. The larvæ, or caterpillars of many species of butterflies, feed on the green plant; and sheep and oxen will readily eat the dried.

URTICA Marina. See ANIMAL-Flower.

USANCE, in commerce, is a determinate time fixed for the payment of bills of exchange, reckoned either from the day of the bills being accepted, or from the day of their date; and thus called because regulated by the usage and custom of the places whereon they are drawn.

USE, in law, the profit or benefit of lands and tenements; or a trust and confidence reposed in a person for the holding of lands, &c. that he to whose use the trust is made shall receive the profits.

USHANT, an island of France, 15 miles west of the coast of Brittany, at the entrance of the British channel.

USHER (James), archbishop of Armagh, one of the most illustrious prelates in the 17th century, as well with respect to his piety and other virtues, as his uncommon erudition, was born in Dublin in 1580, and it is said that two of his aunts taught him to read, though they were both born blind. Dublin college being finished in 1593, he was one of the three first students admitted into it. He made so swift a progress in his studies, that at eighteen years of age he was able to dispute with Henry Fitz-Simon, a famous Jesuit, who challenged all the Protestant clergy; and defended his cause so well in the castle of Dublin, that he made him repent his challenge. He was ordained priest in 1601, and soon after was appointed to preach constantly before the court at Christ church in Dublin,

on Sundays in the afternoon. In 1603, he was sent over to England with Dr Luke Challoner, in order to purchase books for the library of Dublin. In 1607, he took the degree of bachelor of divinity; soon after, he was made chancellor of St Patrick's cathedral, and the same year was chosen professor of divinity, when he made choice of Bellarmine's controversies for the subject of his lectures. Some years after, he made it a constant custom to come over to England once in three years, spending one month of the summer at Oxford, another at Cambridge, and the rest of the time at London. In 1612, he took the degree of doctor of divinity; at the latter end of the year 1620, he was promoted to the bishopric of Meath, and in 1625 was made archbishop of Armagh. In the administration of his archbishopric he acted in a very exemplary manner, and endeavoured to reform the clergy and officers in the ecclesiastical courts. In 1640, he came over to England with his family, with an intention soon to return to Ireland; but was prevented by the rebellion which broke out there in 1641; and in that rebellion he was plundered of every thing, except his library, which was in England, and some furniture in his house at Drogheda. His majesty, therefore, conferred on him the bishopric of Carlisle, to be held in *commendam*: the revenues of which were greatly lessened by the Scots and Irish armies quartering upon it; but when all the lands belonging to the bishoprics in England were seized by the parliament, they voted him a pension of 400 l. *per annum*, though he never received it above once or twice. He afterwards removed to Oxford; and, in 1643, was nominated one of the assembly of divines at Westminster, but refused to sit amongst them: which, together with some of his sermons at Oxford, giving offence to the parliament, they ordered his study of books, of considerable value, to be seized; but by the care of Dr Featly, one of the assembly, they were secured for the primate's use. The king's affairs declined; and Oxford being threatened with a siege, he left that city and retired to Cardiff in Wales, to the house of Sir Timothy Tyrrel, who had married his only daughter, and was then governor and general of the ordnance. He was afterwards invited to London by the countess of Peterborough. In 1647, he was chosen preacher in Lincoln's Inn; and during the treaty in the Isle of Wight, he was sent for by the king, who consulted him about the government of the church. The death of his majesty struck him with great horror. The countess of Peterborough's house, where the primate then lived, being just over-against Charing-Cross, several of her gentlemen and servants went up to the leads of the house, whence they could plainly see what was acting before Whitehall. As soon as his majesty came upon the scaffold, some of the household told the primate of it; and asked him, whether he would see the king once more, before he was put to death. He was at first unwilling, but at last went up: where, as the ceremonial advanced, the primate grew more and more affected; and, when the executioners in vizards began to put up the king's hair, he swooned away; and being carried to his bed, is said to have prophesied what happened in England ever since. He died of a pleurisy, in 1655; and was solemnly buried at Westminster, in St Erasmus's chapel. He

published, 1. *Britannicarum Ecclesiarum Antiquitates*. 2. *Polycarpi et Ignatii Epistolæ, Græce Latine, &c.* 3. *Annals of the Old and New Testament, in Latin.* 4. *De Græce Septuaginta interpretum Versione Syntagma*; and many other books which are esteemed. A considerable number of his works still remain in manuscript.

USHER, an officer or servant who has the care and direction of the door of a court, hall, chamber, or the like.

USHER of the Black Rod, the eldest of the gentlemen ushers, daily waiters at court, whose duty is to bear the rod before the king at the feast of St George and other solemnities.

USK, a river of Wales, which rises on the west of Brecknockshire, and runs south-east through that county and Monmouthshire, falling into the mouth of the Severn.

USQUEBAUGH, a strong compound liquor, chiefly taken by way of dram.

There are several different methods of making this liquor; but the following is esteemed one of the best: To two gallons of brandy, or other spirits, put a pound of Spanish liquorice, half a pound of raisins of the sun, four ounces of currants, and three of sliced dates; the tops of baum, mint, savory, thyme, and tops of the flowers of rosemary, of each two ounces; cinnamon and mace, well bruised, nutmegs, aniseeds, and coriander-seeds, bruised likewise, of each four ounces; of citron or lemon, and orange-peel, scraped, of each an ounce: let all these infuse 48 hours in a warm place, often shaking them together: then let them stand in a cool place for a week: after which the clear liquor is to be decanted off, and to it is to be put an equal quantity of neat white port, and a gallon of canary; after which it is to be sweetened with a sufficient quantity of double-refined sugar.

USTION, in pharmacy, the preparing of certain substances by burning them.

USUFRUIT, in the civil law, the use of enjoyment of any lands or tenements; or the right of receiving the fruits and profits of an inheritance, or other thing, without a power of alienating or changing the property thereof.

USURER, a person charged with a habit or act of usury. See USURY.

USURIOUS CONTRACT, is any bargain or contract whereby a man is obliged to pay more interest for money than the statute allows.

USURPATION, in law, is an injurious using or enjoyment of a thing for continuance of time, that belongs of right to another.

USURY, an unlawful contract upon the loan of money, to receive the same again with exorbitant increase. Under the article INTEREST, it was observed, that by statute 37 Hen. VIII. c. 9. the rate of interest was fixed at 10 l. *per cent. per annum*: which the statute 13 Eliz. c. 8. confirms, and ordains, that all brokers shall be guilty of a *præmunire* that transact any contracts for more, and the securities themselves shall be void. The statute 21 Jac. I. c. 17. reduced interest to 8 l. *per cent.*; and it having been lowered in 1650, during the usurpation, to 6 *per cent.* the same reduction was re-enacted after the restoration by statute 12 Car. II. c. 13. and, lastly, the stat. 12 Ann.

ft. 2. c. 16. has reduced it to 5 per cent. Wherefore not only all contracts for taking more are in themselves totally void, but also the lender shall forfeit treble the money borrowed. Also if any scrivener or broker takes more than 5 s. per cent. procuracion-money, or more than 12 d. for making a bond, he shall forfeit 20 l. with costs, and shall suffer imprisonment for half a year.

UTERUS, in anatomy. See there, n° 372, g.

UTICA (anc. geog.), a town of Africa Propria, on the Mediterranean: a Tyrian colony, and older than Carthage, (Sil. Italicus); its name, according to Bochart, denoting *old*: reckoned second to it; but after the destruction of Carthage, became the capital and centre of all the Roman transactions in Africa, according to Strabo; who adds, that it stood on the same bay with Carthage, at one of the promontories called *Apollonium*, bounding the bay on the west side, the other to the east called *Hermela*, being at Carthage. It became famous by the death of Cato, who thence was called *Uticensis*. Now called *Bijerta*, or a town near the spot on which Utica stood, in the kingdom of Tunis. E. Long. 9° Lat. 37°.

UTRECHT, one of the seven United Provinces, or States of Holland, wholly surrounded by Holland and Guelderland, excepting a small part of it that borders on the Zuyder-Zee. Its greatest length is about 32 miles, and breadth about 22. It enjoys a good air; and in most places the soil is fruitful, but in some sandy, or what is called *turf-ground*, and in others over-run with wood. It is watered by the Leck, Rhine, Vecht, and other smaller rivers, besides several canals; of which that extending from the village of Vreeswyk to Utrecht is one of the chief. The states here, as in the other provinces, are composed of the nobility and the towns; the latter of which are Utrecht, Amersfoort, Wyk, Rhenen, and Montfoort; but Utrecht bears the chief sway. The bishops of that city were anciently temporal lords of the province, as well as of Overysel, till Henry of Bavaria sold the sovereignty thereof to Charles V. In 1559 the see of Utrecht was raised to an archbishopric by Philip II. of Spain. In 1579 it acceded to the alliance of the other provinces, and became a free state. The provincial states are composed of 22 members, and three deputies are sent by them to the assembly of the States-general. The established clergy are divided into three classes, making 79 ministers, of whom a synod is held once a year at Utrecht.

UTRECHT, or Latin, *Ultrajectum*, *Trajectum vetus* or *inferius*, or *Trajectum Rheni*, capital of a province of the same name, so called from its ancient ferry or passage here over the Rhine; the word being compounded of *trecht*, which in Dutch signifies a "ferry," and *oud* or *olt*, i. e. "old." It is a fair, large, and populous city, the capital of the province, and the seat of the states, situated 19 miles from Amsterdam, 25 from Rotterdam, and 27 from Leyden. There were several large and rich monasteries, and other religious houses here, before the Reformation. The churches are magnificent, especially that of St Martin, formerly the cathedral, and usually called the *dome*. Over that of St Salvador or the old minister, where the British have a place of worship, is a museum of all sorts of antiques and rarities. Here is a stately town-house, with a commandery of the Teutonic order, and a celebrated university, which was founded in 1630, since which

it hath flourished greatly, though it has not all the privileges of most other universities; being wholly subject to the magistrates of the city. The mall without the town, having five rows of lofty limes on each side, is very pleasant; and the physic-garden belonging to the university, is extremely curious. There are five churches here that have chapters; but the members of these purchase the places, of which some cost 6000 or 7000 guilders. The streams which run through several of the streets, contribute much to the beauty and cleanliness of the town; and the canal that is cut from the Leck, and passes through it to Amsterdam, will carry ships of any burden. Pope Adrian VI. was a native of this city. Here, in 1579, the memorable union was formed between the seven provinces; and, in 1713, the celebrated peace concluded between France on the one part, and the allies on the other. The Papists have a nominal archbishop of this city; and there is a silk manufactory carried on in it, which employs a number of hands.

VULCAN, in Pagan worship, the god of subterraneous fire and metals, was the son of Jupiter and Juno; and was said to be so remarkably deformed, that his father threw him down from heaven to the isle of Lemnos, in which fall he broke his leg, and there he set up his forge, and taught men how to soften and polish brass and iron. Thence he removed to the Liparian isles, near Sicily, where, by the assistance of the Cyclops, he made Jupiter's thunder-bolts, and armour for the other gods. Notwithstanding the deformity of his person, he had a passion for Minerva, and by Jupiter's consent made his addresses to her, but without success. He was, however, more fortunate in his suit to Venus; who, after her marriage, chose Mars for her gallant; when Vulcan exposed them to the ridicule of the other gods, by taking them in a net.

He had several names: that of *Lemnius*, from the isle of Lemnos; *Mulcher*, or *Mulcifer*, from his art of softening steel and iron; and (among the Greeks) *Hephaistos*, from his delighting in flames. In the ancient medals of the Greeks and Romans, he is represented as a lame, deformed, and squalid man, working at the anvil, and attended by the Cyclops, or by some other god or goddess who comes to his assistance. But the Egyptians represented him as proceeding out of an egg placed in the mouth of Jupiter, to express the radical and natural heat diffused through all created beings.

It was customary with many nations after a victory, to gather the enemies arms in a heap, and offer them to Vulcan. His principal temple was in a consecrated grove, at the foot of mount *Ætna*, guarded by dogs, who are said to have had such sagacity as to distinguish his votaries, to fawn upon the virtuous, and to tear the vicious to pieces.

VULCANO, in natural history. See VOLCANO.

VULGATE, a very ancient Latin translation of the Bible, and the only one acknowledged by the church of Rome to be authentic. See BIBLE.

VULNERARY, in medicine, an epithet given to remedies proper for the cure of wounds and ulcers.

VULTUR, a genus of birds belonging to the order of accipitres. The beak is straight and crooked at the point; the head has no feathers; on the forehead being only naked skin; and the tongue is bifid. There are eight species. The most remarkable are,

1. The condor, which is not only the largest of this genus, but perhaps of all others which are able to fly. The accounts of authors in regard to its extent of wing are various, viz. from 9 to 18 feet, from the tip of one wing to that of the other. One gives it strength sufficient to carry off sheep, and boys of 10 years old; while another ventures to affirm, that it can lift an elephant from the ground high enough to kill it by the fall! M. de Salerne says, that one of this kind was shot in France in the year 1719, which weighed 18 lib. and whose extent of wing was 18 feet. But to come nearer the truth, perhaps it is better to abide by descriptions which bear a moderate proportion. In Hawkefworth's Voyages, mention is made of one of these birds shot at Port Desire, off Penguin Island, of which he gives the following description: "The head of this bird resembled that of an eagle, except that it had a large comb upon it. Round the neck it had a white ruff, exactly resembling a lady's tippet; the feathers on the back were as black as jet, and as bright as the finest polish could render that mineral: the legs were remarkably strong and large, and the talons like those of an eagle, except that they were not so sharp; and the wings when they were extended, measured, from point to point, no less than 12 feet." This last account seems by no means to exceed the natural size, since we have an account in the Philosophical Transactions of one of the quill-feathers of this bird, brought from Chili, which measured 12 feet 4 inches; the diameter of the quill half an inch; and the extent of wing 16 feet. This bird was met in lat. 33 south, not far from the island Mocha, in the South Sea, in the year 1691. The seamen shot it on a cliff by the sea-side; and taking it for a kind of turkey, made a meal of it. In this account we are told that the colour was black and white, like a magpie, and the crest, or comb, sharp like a razor.

It has been supposed, that these birds were peculiar to South America: but Buffon believes they are likewise inhabitants of Asia and Africa, and not unlikely of Europe also, if the lacmerger of the Germans be the same bird, which he seems inclined to think; and that the roc, or ruch, mentioned frequently in the Arabian Tales, may also prove to be the same.

Alberto Fortis, in his travels into Dalmatia in the year 1778, p. 245, says, that he measured a vulture himself, (one found near the mouth of the Cetina) whose extent of wings was above 12 feet; and in a note below says, that the sort found in the Swiss mountains, called *le vautour des Alpes*, is of the same race. We further learn, that the throat of the condor is naked, that is, bare of feathers, and of a red colour; the comb brown, but not indented; that in some the upper parts are variegated with black, grey, and white; and under the belly scarlet, as was that bird mentioned by Mr Salerne. Mr Brisson observes, that these birds vary in colour; which will account for the difference in the plumage by which authors have described them: which circumstance frequently happens in other birds, as well as in this species.

2. The phœnicopterus, or Egyptian vulture, is thus described by Mr Hæffelquist. They light in great flocks on the lay-stalls near the city of Cairo, and there promiscuously feed, together with the dogs and other brats, on dead carcases and other offal. They assemble with the kites every morning and evening, in the square

called *Rohndli*, below the cistern (which is the place for executing capital offenders) there to receive the alms of fresh meat, left them by the legacies of wealthy great men.

The appearance of this bird is as horrid as can well be imagined, viz. the face is naked and wrinkled; the eyes are large and black; the beak black and hooked; the talons large, and extending ready for prey; and the whole body polluted with filth: these are qualities enough to make the beholder shudder with horror. Notwithstanding this, the inhabitants of Egypt cannot be enough thankful to Providence for this bird. All the places round Cairo are filled with the dead bodies of asses and camels; and thousands of these birds fly about, and devour the carcases before they putrify and fill the air with noxious exhalations. The inhabitants of Egypt, and after them Maillet in his Description of Egypt, say, that they yearly follow the caravan to Mecca, and devour the filth of the slaughtered beasts, and the carcases of the camels which die on the journey; but we were not eye-witnesses of this. They do not fly high, nor are they afraid of men. If one is killed, all the rest surround him in the same manner as do the royston-crows; they do not quit the places they frequent though frightened by the explosion of a gun, but immediately return thither. Maillet imagines this bird to be the ibis of the ancients: but it is scarcely to be imagined, that a wise nation should pay such honours to an unclean, impure, and rapacious bird, which was not perhaps so common before the Egyptians filled the streets with carcases. If the ibis is to be found, it must certainly be looked for in the order of grallæ of Linnæus; and we imagine it to be the white stork, (*Ardea ciconia*), which is so common in Egypt. The Arabians call it *rochemes*; the French living in Egypt, give it the name of *chapon de Pharaon*, or *de Mahometh*.

3. The aura, or carrion vulture, according to Mr Latham, is about the size of a turkey, though it varies in size in different parts. The bill is white; the end black; irides blueish saffron-colour. The head, and part of the neck, are bare of feathers; and of a red, or rather rufous colour. The sides of the head warted, not unlike that of a turkey. The whole plumage is brown black, with a purple and green gloss in different reflections; but in some birds, especially young ones, greatly verging to dirty brown. The feathers of the quills and tail are blacker than the rest of the body. The legs are flesh-colour; the claws black.

This bird is very common in the West Indies, and both North and South America. It feeds on dead carcases, snakes, &c. like most of this genus; which makes the smell of it very offensive. In general, it is very tame in its wild state; but particularly so, when trained up from being young. This our author experienced in two birds sent home from Jamaica. They were suffered to run wild about the garden, and were alert and brisk during the summer months: but impatient of the least cold; for a rainy day, with the slightest degree of cold, obliged them to creep for shelter. In the West Indies they roost together of nights, in vast numbers, like rooks in this country. They are reckoned a most useful animal in the places where they resort; which secures their safety, added to a penalty for killing one, which is in force in Jamaica and other islands of the West Indies.

4. The *Agittarius*, or secretary, is a most singular species, being particularly remarkable from the great length of its legs; which at first sight would induce one to think it belonged to waders: but the characters of the vulture are so strongly marked throughout, as to leave no doubt to which class it belongs.

The bird, when standing erect, is full three feet from the top of the head to the ground. The bill is black, sharp, and crooked, like that of an eagle; the head, neck, breast, and upper parts of the body, are of a bluish ash colour: the legs are very long, stouter than those of a heron, and of a brown colour; claws shortish, but crooked, not very sharp, and of a black colour; from the hind-head springs a number of long feathers, which hang loose behind like a pendent crest; these feathers arise by pairs, and are longer as they are lower down on the neck; this crest the bird can erect or depress at pleasure; it is of a dark colour, almost black; the webs are equal on both sides, and rather curled; and the feathers, when erected, somewhat incline towards the neck; the two middle feathers of the tail twice as long as any of the rest.

This singular species inhabits the internal parts of Africa, and is frequently seen at the Cape of Good Hope. It is also met with in the Philippine islands.

The description was taken by Mr Latham from three that were alike, which he saw in England alive, some years since; two of which are now in the Leverian museum. From confinement, they had lost their two long tail-feathers; but this want was supplied by some accurate drawings by Mr Banks, taken from the life at the Cape.

As to the manners of this bird, it is on all hands allowed that it principally feeds on rats, lizards, snakes, and the like; and that it will become familiar: whence Sonnerat is of opinion that it might be made useful in some of our colonies, if encouraged, towards the destruction of those pests. They call it at the Cape of Good Hope, *slangeater*, i. e. snake-eater. A great peculiarity belongs to it, perhaps observed in no other;

which is, the faculty of striking forwards with its legs, never backwards. Dr Solander has seen one of these birds take up a snake, small tortoise, or such like, in its claws; when dashing it from thence against the ground with great violence, if the victim was not killed at first, it repeated the operation till that end was answered; after which it ate it up quietly. Dr J. R. Forster mentioned a further circumstance, which he says was supposed to be peculiar to this bird; that should it by any accident break the leg, the bone would never unite again.

VULVA, in anatomy. See there, n° 372.

UVULA, in anatomy. See there, n° 366.

UZ, or Urtz, the country and place of residence of Job. In the genealogy of the patriarchs there are three persons called *Uz*, either of which might give this district its name. The first was the grandson of Sem, by his son Aram, Gen. xxii. 23. who, according to Josephus, occupied the Trachonitis, and Damascus, to the north of Palestine: but Job was among the sons of the East. Another *Uz* was the son of Nahor, Abraham's brother, Gen. x. 21. who appears to have removed after passing the Euphrates, from Haran of Mesopotamia to Arabia Deserta. The third *Uz* was a Horite, from mount Seir, Gen. xxxvi. 28. and thus not of Eber's posterity. Now the question is, from which of these Job's country, *Uz*, took its name. Not from the first, as is already shown: nor from the second, because his country is always called *Seir*, or *Edom*, never *Uz*; and then called a *south*, not an *east*, country, in Scripture. It therefore remains, that we look for the country and place of residence of Job in Arabia Deserta; for which there are very probable reasons. The plunderers of Job are called *Chaldeans* and *Sabeans*, next neighbours to him. These Sabeans came not from Arabia Felix, but from a nearer Sabe in Arabia Deserta, (Ptolemy); and his friends, except Eliphaz the Themanite, were of Arabia Deserta.

UZBECK TARTARY. See TARTARY.

W.

W or w, is the 21st letter of our alphabet; and is composed, as its name implies, of two v's. It was not in use among the Hebrews, Greeks, or Romans; but chiefly peculiar to the northern nations, the Teutones, Saxons, Britons, &c. But still it is not used by the French, Italians, Spaniards, or Portuguese, except in proper names and other terms borrowed from languages in which it is originally used, and even then it is sounded like the single v. This letter is of an ambiguous nature; being a consonant at the beginning of words, and a vowel at the end. It may stand before all the vowels except *u*; as *water*, *wedge*, *winter*, *wonder*: it may also follow the vowels *a*, *e*, *o*, and unites with them into a kind of double vowel, or diphthong; as in *saw*, *few*, *cow*, &c. It also goes before *r*, and

follows *s* and *th*; as in *wrath*, *swear*, *thwart*: it goes before *b* also, though in reality it is sounded after it; as in *when*, *what*, &c. In some words it is obscure, as in *shadow*, *widow*, &c.

WAAG, a river of Hungary, which rises in the Carpathian mountains, on the confines of Poland, and running first from east to west, then turns south, and passing by Leopoldstadt, falls into the Danube, opposite to the island of Schut.

WAAL, a river of the United Netherlands, being one of the branches of the Rhine, which runs from east to west, through the Betu, in the province of Guelderland, passing by Nimeguen, Tiel, Bommel, and Gorcum; and continuing its course eastward, unites its waters with the Maas, and passing by Dort, falls

Wadd
Wake.

into the German Sea below the Briel.

WADD, or WADDING, is a stopple of paper, hay, straw, or the like, forced into a gun upon the powder, to keep it close in the chamber; or to put up close to the shot, to keep it from rolling out.

WADSET, in Scots law. See LAW, N° clxix. 1.

WAFERS, or Sealing WAFERS, are made thus: Take very fine flour, mix it with glair of eggs, isinglass, and a little yeast; mingle the materials; beat them well together; spread the batter, being made thin with gun-water, on even tin-plates, and dry them in a stove; then cut them out for use.

You may make them of what colour you please, by tinging the paste with brazil or vermilion for red; indigo or verditer, &c. for blue; saffron, turmeric, or gamboge, &c. for yellow.

WAGER of LAW. See (*Wager of*) LAW.

WAGER of BATTLE. See (*Wager of*) BATTLE.

WAGGON, a wheel-carriage, of which there are various forms, accommodated to the different uses they are intended for. The common waggon consists of the shafts or rails, being the two pieces which the hind-horse bears up; the welds; the slates, or cross pieces, which hold the shafts together; the bolster, being that part on which the fore-wheels and the axle-tree turn in wheeling the waggon across the road; the chest or body of the waggon, having the staves or rails fixed thereon; the bales, or hoops, which compose the top; the tilt, the place covered with cloth, at the end of the waggon. See MECHANICS, n° 58.

WAGTAIL, in ornithology. See MOTACILLA.

WAIFS, *bona waviata*, are goods stolen, and waived or thrown away by the thief in his flight, for fear of being apprehended. These are given to the king by the law, as a punishment upon the owner for not himself pursuing the felon, and taking away his goods from him. And therefore if the party robbed do his diligence immediately to follow and apprehend the thief (which is called *making fresh suit*), or do convict him afterwards, or procure evidence to convict him, he shall have his goods again. Waived goods do also not belong to the king, till seized by somebody for his use; for if the party robbed can seize them first, though at the distance of 20 years, the king shall never have them. If the goods are hid by the thief, or left any where by him, so that he had them not about him when he fled, and therefore did not throw them away in his flight; these also are not *bona waviata*, but the owner may have them again when he pleases. The goods of a foreign merchant, though stolen and thrown away in flight, shall never be waifs: the reason whereof may be, not only for the encouragement of trade, but also because there is no wilful default in the foreign merchant's not pursuing the thief, he being generally a stranger to our laws, our usages, and our language.

WAIGRATS STRAITS, situated between Nova Zembla and Russia, through which the Dutch failed to the north, as high as 75°; in order to discover a north-east passage to China and the East Indies.

WAINSCOT, in building, the timber-work that serves to line the walls of a room, being usually made in panels, and painted, to serve instead of hangings.

WAKE, the print or track impressed by the course of a ship on the surface of the water. It is formed by the reunion of the body of water which was separa-

ted by the ship's bottom whilst moving through it; and may be seen to a considerable distance behind the stern, as smoother than the rest of the sea. Hence it is usually observed by the compass, to discover the angle of lee-way.

A ship is said to be in the wake of another when she follows her on the same track, or a line supposed to be formed on the continuation of her keel.

Two distant objects observed at sea are called in the wake of each other, when the view of the farthest is intercepted by the nearer; so that the observer's eye and the two objects are all placed upon the same right line.

WAKE is the eve-feast of the dedication of churches, which is kept with feasting and rural diversions. Concerning the origin of wakes we have the following dissertation in Mr Whitaker's History of Manchester.

"Before a building could be used for divine offices, it was required to be consecrated by the bishop, formally sequestered from all secular applications, and dedicated to the purposes of public devotion. And every church at its consecration received the name of some particular personage, who was celebrated in the written annals or the traditional history of Christianity, and whose name had been admitted into that great roll of ecclesiastical fame, the kalendar of the church. This custom was practised among the Roman Britons; and they had the church of St Martin at Canterbury, and that of St Michael at Manchester. It was also continued among the Saxons; and the Saxon churches in York, London, and Manchester, were distinguished by the names of *St Peter, St Paul, and St Mary*. And in the council which was held at Cealchythe in 816, the name of the denominating saint was expressly required to be inscribed on the altars, and also on the walls of the church or a tablet within it.

"The feast of this saint became of course the festival of the church. And the connection betwixt the church and saint being enhanced by the fancifulness of superstition, and the former supposed to be under the patronage of the latter, the parishioners would naturally consider the day of their spiritual guardian with particular respect, and celebrate it with peculiar festivity. This conduct would as naturally be encouraged by the civil and ecclesiastical governors, because it substituted innocent and Christian festivals in the room of the impious and idolatrous anniversaries of heathenism. The common people, generally in all countries as much attached to the festivals as they are devoted to the principles of any religion, finding their annual feasts return as before, and being now able to join in them without guilt, would be the sooner weaned from their idolatrous attachments. And this would be the natural operation of the affections, equally on the continent and in the island, and equally among the Britons and Saxons. Thus, at the first commencement of Christianity among the Jutes of Kent, and with a view to promote the conversion of them and the rest, Gregory prudently advised what had been previously done among the Britons, Christian festivals to be instituted in the place of the idolatrous, and the suffering-day of the martyr whose relics were deposited in the church, or the day on which the building was actually dedicated, to be the established feast of the parish. Both were appointed and observed. And they were observed and appointed as distinct festivals. Bishop Ken-

Wake.

Wake.

net indeed, in his sensible account of our wakes, has invariably confounded them, and attributed to the day of dedication what is true only concerning the faint's day. But they were fully distinguished at first among the Saxons; as appears from the laws of the Confessor, where the *Dies Dedicatio* or *Dedicatio* is repeatedly discriminated from the *Propria Festivitas Sancti*, or *Celebratio Sancti*. And they remained equally distinct to the Reformation: the dedication-day in 1536 being ordered for the future to be kept on the first Sunday in October, and the festival of the patron-saint to be celebrated no longer.

"But the former could never have been observed by the people with the same regard as the latter. That was merely a feast commemorative of the church's commencement; and this was one previously kept by the nation in general, and the day of their own faint in particular. This therefore, in a high strain of pre-eminence over the other, was actually denominated the *church's holiday*, or its peculiar festival. And while this remains in many parishes at present, the other is so utterly annihilated in all, that the learned and sensible antiquary whom I have mentioned before, actually knew nothing of its distinct existence, and absolutely confounded it with this.

"Thus instituted at first, the day of the tutelar faint was observed, most probably by the Britons, and certainly by the Saxons, with great devotion. And the evening before every faint's day, in the Saxon-Jewish method of reckoning the hours, being an actual part of the day, and therefore like that resigned to the duties of public religion, as they reckoned Sunday from the first to commence at the sunset of Saturday; the evening preceding the church's holiday would be observed with all the devotion of the festival. The people actually repaired to the church, and joined in the services of it. And they thus spent the evening of their greater festivities in the monasteries of the north, as early as the conclusion of the 7th century. In that of Rippon, and on the anniversary of Wilfrid particularly, we see the bishops, abbots, and numerous trains of attendants, all convened at the monastery in order to celebrate the day, and all assembled the evening before it at the prayers of the church. And these services were naturally denominated from their late hours *peccan*, or "wakes," and *vigils*, or "eves." That of the anniversary at Rippon, as early as the commencement of the 8th century, is expressly denominated the *vigil*. But that of the church's holiday was named the *peccan*, or "church-wake," the *church-vigil*, or "church-eve." And it was this commencement of both with a wake which has now caused the days to be generally preceded with vigils, and the church-holiday particularly to be denominated the *church-wake*. So religiously was the eve and festival of the patron-saint observed for many ages by the Saxons; even as late as the reign of Edgar, the former being spent in the church and employed in prayer. And the wake, and all the other holidays in the year, were put upon the same footing with the octaves of Christmas, of Easter, and of Pentecost; and any persons repairing to the celebration of the day were, as all ordinarily resorting to the church were, under the immediate protection of the king, and consequently free from arrests in their way to and return from it.

I

Wake.

"When Gregory recommended the festival of the patron-saint, he also recommended something more adapted to gain a general reception than religious acts and exercises. He advised, that the people should be encouraged on the day of the festival to erect booths of branches about the church, and to feast and be merry in them with innocence. And as the authority of Gregory would certainly cause the encouragement to be given, so the smallest would be effectual. Nor would such churches only as had previously been heathen temples, but all immediately have the day of their guardian saint observed with this open festivity. As the people had been all idolaters, the reason would be equally forcible for one parish as another. And the strong tendency of the common people to every sensitive enjoyment would make the practice universal. In every parish, on the returning anniversary of the faint, little pavilions were constructed of boughs; and the immediate neighbourhood of St Michael's, and the church-yard of St Mary's, resounded with the voice of hospitality and the notes of merriment.

"But few persons are ever to be intrusted to feast; and fewer are to be allowed to meet in numbers together. There is a contagious viciousness in crowds. Though each individual among them, alone by himself, would act with a religious propriety; yet all together they act with irreligion and folly. The fire imperceptibly runs from breast to breast; each contributes to swell the tide of spirits beyond its proper bounds, and wickedness and absurdity enter at the breach that is made in reason. And this viciousness is always augmented in its force, when the grosser spirits, that are merely the result of feasting, mingle and ferment the tide. The feasting of the faint's day was soon abused. And it seems to have been greatly so before the reign of Edgar, as the intemperance of the festival was then creeping even into the vigil, and even mixing with the offices of religion. In the very body of the church, when the people were assembled for devotion, they were beginning to mind diversions and introduce drinking. And so gross an abuse of the eve could have stolen in only from the licentiousness of the festival. The growing intemperance would gradually stain the service of the vigil, till the festivity of it was converted, as it now is, into the rigour of a fast. These disorders would be less obnoxious on the day itself, because they did not intrude within the church and profane the prayers. But they were certainly greater, and went on increasing in viciousness and folly, till they too justly scandalized the puritans of the last century; and numbers of the wakes were diffused entirely. Our own has been long discontinued. It was abolished in 1536 by the laws of Henry VIII. which appears to have had little or no influence on the general practice. It was put down by a particular and local order in 1579, and forgotten in the long and rigid reign of puritanism that was then commencing at Manchester. And Henry earl of Derby, Henry earl of Huntingdon, William lord bishop of Chelms, and others of the high commission under queen Elizabeth, assembled at Manchester in 1579; issued orders against pipers and minstrels playing, making and frequenting ales, bear-baitings and bull-baitings on the Sunday, or any other day of the week in time of divine service or sermons; and prohibited for the future all superfluous and superstitious

Wake.

tious ringing, common feasts, and wakes. But the wake of the neighbouring parish of Eccles is celebrated among us to the present day; and a considerable number of people resort to it annually from our own and the adjoining parishes.

"This custom of celebrity in the neighbourhood of the church on the days of particular saints, was introduced into England from the continent, and must have been familiar equally to the Britons and Saxons; being observed among the churches of Asia in the 6th century, and by those of west Europe in the 7th. And equally in Asia and Europe, equally on the continent and in the island, these celebrities were the causes of those commercial marts which we denominate *fairs*. See FAIRS. The people resorted in crowds to the festival, and a considerable provision would be wanted for their entertainment. The prospect of interest invited the little traders of the country to come and offer their wares, and the convenience of the accommodation promoted a vigorous sale among the people. And other traders were induced by the experience of these, to bring in different articles, and hope for an equal sale. Thus among the many pavilions for hospitality in the neighbourhood of the church, various booths were erected for the sale of commodities. In large towns surrounded with populous districts, the resort of the people to the wake would be great, and the attendance of traders at the celebrity numerous. And this resort and this attendance constitute a fair. Basil expressly mentions the numerous appearance of traders at these festivals in Asia; and Gregory notes the same custom to be common in Europe. And as the festival was observed on a feria or holiday, it naturally assumed to itself, and as naturally communicated to the mart, the appellation of *feria* or *fair*; the same among the Saxons, the French, the Germans, and the Britons, *seger*, *foire*, *fyers*, and *faires*: the word was derived from the same source in all these nations, the one ecclesiastical language of West Europe at this period. And several of our most ancient fairs appear to have been actually held, and have been actually continued to our time, on the original church-holidays of the places; as that on the festival of St Peter, at St Peter's church in Westminster; another on the feast of St Cuthbert, at St Cuthbert's in Durham; and a third on the holiday of St Bartholomew, at St Bartholomew's in London."

WAKE (William), archbishop of Canterbury, was born in 1657, and educated at Oxford. When he entered into holy orders, he was appointed preacher to the society of Gray's Inn; and in the reign of James II. attended lord Preston, ambassador to France, as his chaplain. Upon his return to England, he distinguished himself by several tracts against Popery; particularly against the bishop of Meaux's Exposition of the Doctrine of the Catholic Church. After the revolution, he was appointed deputy-clerk of the closet, and chaplain in ordinary to king William and queen Mary, and the year following was made canon of Christchurch. In 1694 he was collated to the rectory of St James's, Westminster; and in 1701 was installed dean of Exeter. In 1705 he was consecrated to the see of Lincoln, and in 1715-16, translated to the archbishopric of Canterbury. He died at Lambeth in 1737. Beside sermons, he published several pieces, particularly

an English version of the Genuine Epistles of the Apostolical Fathers, &c.

WALACHIA, a province of Turkey in Europe, bounded by the Irontage mountains, which separate it from Transylvania on the north-west, by Moldavia on the north-east, by the Danube, which separates it from the province of Servia, on the south-west. It is 225 miles in length, and 125 in breadth where it is broadest. In the last war between the Turks and Germans, the latter having lost the fatal battle of Crozka, were obliged to give up this district to the Turks, by the treaty of Belgrade concluded in 1739. The air is good, and the soil fruitful; producing corn, wine, oil, pastures, and all manner of European fruit; and has abundance of oxen and sheep, and an excellent breed of horses. The inhabitants are indulged with the free exercise of their religion, which is of the Greek church; and this circumstance renders them the more contented with their masters; because if the Roman Catholics had the ascendant, they would be sure of undergoing persecution.

WALCHEREN, an island of the Low Countries, and one of the principal of those of Zealand; being separated from the islands of North and South Beveland by a narrow channel, and from Dutch Flanders by the mouth of the Scheld. It is about nine miles in length, and eight in breadth; and though it lies low, has good arable and pasture land. The chief town of this island and the whole province is Middelburg.

WALDEN, a town of Essex, commonly called *Saffron Walden*, with a market on Saturdays, and two fairs on Mid-lent Saturday for horses, and November 1st for cows. It is remarkable for the plenty of saffron that grows about it, from which the owners derive great profit. This town was incorporated by Edward VI. and is governed by a mayor and 24 aldermen. It is 27 miles north-west-by-north of Chelmsford, and 43 north-east of London. E. Long. o. 15. N. Lat. 52. 5.

WALDO, a merchant of Lyons in the latter part of the 12th century, who applying himself to the study of the Scriptures, and finding no warrant there for several of the Romish doctrines, particularly that of transubstantiation, publicly opposed them. His followers, who from him were called *Waldenses*, being chased from Lyons, spread over Dauphine and Provence; upon which Philip II. is said to have razed 300 gentlemen's seats, and destroyed several walled towns, to stop their growth: but this, instead of suppressing, spread them over a great part of Europe. The articles of their faith, which they drew up and dedicated to the king of France, agreed in most points with those of the present Protestants. In the year 1200, those of them in the province of Albigeois in Languedoc, from whence they were called *Albigenses*, stood upon their defence; upon which Philip drove them into Bohemia, Savoy, and England. The crusade against them is said to have consisted of 500,000 men, who wore their crosses on their breasts, to distinguish themselves from those who went to the Holy Land, and wore them on their shoulders.

WALES, a county situated in the south-west part of Britain, into which the ancient Britons retired from the persecution of the Saxons. Anciently it was of greater extent than it is at present, and comprehended

Walachia
||
Wales.

all the country beyond the Severn, that is, besides the twelve counties included in it at present, those of Herefordshire and Monmouthshire, which now are reckoned a part of England, were then inhabited by three different tribes of the Britons, namely, the Silures, the Demetæ, and the Ordovices. The Romans were never able to subdue them, till the reign of Vespasian, when they were reduced by Julius Frontinus, who placed garrisons in their country to keep them in awe. Though the Saxons made themselves masters of all England, they never could get possession of Wales, except the counties of Monmouthshire and Herefordshire, formerly a part of Wales. About the year 870, Roderic king of Wales divided it among his three sons; and the names of these divisions were, *Demetia*, or *South-Wales*; *Preafia*, or *Powis-Land*; and *Venedotia*, or *North-Wales*. Another division is mentioned afterwards in the records, viz. North Wales, South Wales, and West Wales; the last comprehending the counties of Monmouth and Hereford. The country derived the name of *Wales*, and the inhabitants that of *Welsh*, from the Saxons, who by those terms denote a country and people to which they are strangers; for the Welsh, in their own language, call their country *Cymry*, and their language *Cymraeg*. They continued under their own princes and laws from the above-mentioned period, and were never entirely subjected to the crown of England till the reign of Edward I. when Llewellyn ap Gryffith, prince of Wales, lost both his life and dominions. Edward, the better to secure his conquest, and to reconcile the Welsh to a foreign yoke, sent his queen to lie-in at Caernarvon, where she was delivered of a prince; to whom the Welsh, on that account, the more readily submitted. Ever since that time the eldest sons of the kings of England have commonly been created princes of Wales, and as such enjoy certain revenues from that country. But though Wales, from that time, was subject to the crown of England, yet it was not united and incorporated with it till the 27th of Henry VIII. when, by act of parliament, the government of it was modelled according to the English form; all laws, customs, and tenures contrary to those of England being abrogated, and the inhabitants admitted to a participation of all the English liberties and privileges, particularly that of sending members to parliament, viz. a knight for every shire, and a burgess for every three-town, except Merioneth. By other acts made afterwards, the country was divided into four circuits, and two justices were appointed for each, containing three counties; but at present there are only two circuits and four judges, two for each. In fine, the government here, both civil and ecclesiastical, is now the same as that of England.

As to the character of the Welsh, they are said to be a brave, hospitable people; and though very jealous of affronts, passionate, and haughty, yet are easily reconciled. The common people look with a suspicious eye on strangers, and bear an hereditary grudge to the English nation, by whom their ancestors were expelled from the finest parts of the island. The gentlemen are apt to value themselves upon the antiquity of their families; and with some reason, as they can generally trace them much higher than the inhabitants of most other countries.

All the better sort, both in town and country, can speak English, especially in the counties bordering upon England. The common people, in general, only speak their own language, which is the ancient British; and not only differs entirely from the English, but has very little affinity with any of the western tongues, unless we should except the Galic, Erie, or Irish. It is said to be a dialect of the ancient Celtic or Gomerian, and in many respects to resemble the Hebrew. Most of the clergy are natives of the country, and understand English so well, that they could exercise their functions in any part of Britain. The public worship, however, is as often performed in the Welsh as in English, excepting in the towns, where the latter is the prevailing language; nay, there, even most of the meaner sort understand it. The inhabitants, who are computed at about 300,000, are not, in general, wealthy, though the land-tax of Wales brings in 437,521.

The country, though mountainous, especially in North Wales, is far from being barren or unfruitful; the hills, besides the metals and minerals they contain, feeding vast herds of small black cattle, deer, sheep, and goats, and their valleys abounding in corn, as their seas and rivers do in fish. Here are also wood, coal, and turf for fuel, in abundance.

Wales is bounded on all sides by the sea and the Severn; except on the east, where it joins to the counties of Chester, Salop, Hereford, and Monmouth. Its length, from the southernmost part of Glamorganshire to the extremity of Flintshire north, is computed at about 113 miles; and its greatest breadth, from the river Wye east to St David's in Pembrokeshire west, is nearly of the same dimensions, being about 90 miles.

After the conquest of Wales by Edward I. very material alterations were made in divers parts of their laws, so as to reduce them nearer to the English standard, especially in the forms of their judicial proceedings: but they still retained very much of their original polity, particularly their rule of inheritance, viz. that their lands were divided equally among all the issue male, and did not descend to the eldest son alone. By other subsequent statutes their provincial immunities were still farther abridged: but the finishing stroke to their dependency was given by the statute 27 Hen. VIII. c. 26. which at the same time gave the utmost advancement to their civil prosperity, by admitting them to a thorough communication of laws with the subjects of England. Thus were this brave people gradually conquered into the enjoyment of true liberty; being insensibly put upon the same footing, and made fellow-citizens with, their conquerors.

It is enacted by this statute, 27 Hen. VIII. 1. That the dominion of Wales shall be for ever united to the kingdom of England. 2. That all Welshmen born shall have the same liberties as other king's subjects. 3. That lands in Wales shall be inheritable according to the English tenures and rules of descent. 4. That the laws of England, and no other, shall be used in Wales: besides many other regulations of the police of this principality. And the statute 34 & 35 Hen. VIII. c. 26. confirms the same, adds farther regulations, divides it into twelve shires, and, in short, reduces it into the same order in which it stands at this day; differing from the kingdom of England in only a few particulars, and those too of the nature of pri-

Wales
Wall.

privileges, (such as having courts within itself, independent of the procefs of Weftminster-hall), and fome other immaterial peculiarities, hardly more than are to be found in many counties of England itfelf.

When the polity of Wales was fettled in the reign of Hen. VIII. private courts of a limited, though extenfive, jurifdiction were erected all over the country; principally by the ftatute 34. & 35 Hen. VIII. c. 26. though much had before been done, and the way prepared by the ftatute of Wales, 12 Edw. I. and other ftatutes. By the ftatute of Henry the Eighth before-mentioned, courts-baron, hundred, and county courts, are there eftablifhed as in England. A feffion is alfo to be held twice in every year in each county, by judges appointed by the king, to be called the *great feffions of the feveral counties in Wales*: in which all pleas of real and perfonal actions fhall be held, with the fame form of procefs and in as ample a manner as in the court of common pleas at Weftminster: and writs of error fhall lie from judgments therein (it being a court of record) to the court of king's bench at Weftminster. But the ordinary original writs or procefs of the king's court at Weftminster do not run into the principality of Wales; though procefs of execution does: as do alfo all prerogative writs, as writs of *certiorari*, *quo minus*, *mandamus*, and the like. And even in caufes between fubject and fubject, to prevent injuftice through family-factions and prejudices, it is held lawful (in caufes of freehold at leaft, if not in all others) to bring an action in the Englifh courts, and try the fame in the next Englifh county adjoining to that part of Wales where the caufe arifes. But, on the other hand, to prevent trifling and frivolous fuits, it is enacted by ftatute 13 Geo. III. c. 51. that in perfonal actions, tried in any Englifh county where the caufe of action arofe, and the defendant refides in Wales, if the plaintiff fhall not recover a verdict for ten pounds, he fhall be nonfuit and pay the defendant's cofts, unlefs it be certified by the judge that the freehold or title came principally in queftion, or that the caufe was proper to be tried in fuch Englifh county. And if any tranfitory action, the caufe whereof arofe and the defendant is refident in Wales, fhall be brought in any Englifh county, and the plaintiff fhall not recover a verdict for ten pounds, the plaintiff fhall be nonfuit, and fhall pay the defendant's cofts, deducting thereout the fum recovered by the verdict.

Prince of WALES. See *ROYAL FAMILY*.

WALKING. Celfus fays that walking, reading moderately loud, fencing, and playing with the ball, all ftrengthen a weak ftomach. Walking, he fays, is beft if it is up and down hill, except in cafes of great weaknefs; becaufe afcending and defcending exercifes the whole body more than the plain does. If the vifcera are weak, riding is to be preferred to walking. Walking preferves, and riding recovers health the beft.

WALKING Leaf. See *MANTIS SPECIOSA*.

WALL, in architecture, the principal part of a building, as ferving both to inclofe it, and to fupport the roof, floors, &c.—Walls are diftinguifhed into various kinds, from the matter whereof they confift; as plattered or mud-walls, brick-walls, ftone-walls, flint or boulder-walls, and boarded-walls. See *ARCHITECTURE*.

WALLACE (Sir William) a gallant general of the Scots, who endeavoured to refcue his country from the Englifh yoke; but being taken prifoner, he was unjuftly tried by the Englifh laws, condemned, and executed as a traitor to Edward I. in 1304. See *SCOTLAND*, n° 1033. *et feq.*

WALLACHIA. See *WALACHIA*.

WALLER (Edmund), a celebrated Englifh poet, was the fon of Robert Waller, Efq; of Agmondefham in Buckinghamfhire, by Anne, the fiftler of the great Hamden, who diftinguifhed himfelf fo much in the beginning of the civil wars. He was born in 1605; and his father dying when he was very young, the care of his education fell to his mother, who fent him to Eton fchool. He was afterwards fent to King's college in Cambridge, where he muft have been very affluous in his ftudies, fince, at fixteen or feventeen years of age, he was chofen into the laft parliament of King James I. and ferved as burgefs for Agmondefham. He began to exercife his poetical talent fo early as the year 1623; as appears from his verfes "upon the danger his majesty (being prince) efcape'd in the road of St Andro;" for there Prince Charles, returning from Spain that year, had like to have been caft away. It was not, however, Mr Waller's wit, his fine parts, or his poetry, that fo much occafioned him to be firft publicly known, as his carrying off the daughter and fole heirs of a rich citizen, againft a rival whole intereft was efpoufed by the court. It is not known at what time he married his firft lady; but he was a widower, before he was 25, when he began to have a paffion for Sachariffa, which was a fictitious name for the lady Dorothy Sidney, daughter to the earl of Leicefter, and afterwards wife to the earl of Sunderland. He was now known at court, careffed by all who had any relifh for wit and polite literature; and was one of the famous club of which the Lord Falkland, Mr Chillingworth, and other eminent men, were members. He was returned burgefs for Agmondefham in the parliament which met in April 1640. An intermiffion of parliaments having difgufted the nation, and raifed jealousies againft the defigns of the court, which would be fure to difcover themfelves whenever the king came to ask for a fupply, Mr Waller was one of the firft who condemned the preceding meafures. He fhewed himfelf in oppofition to the court, and made a fpeech in the houfe on this occafion; from which we may gather fome notion of his general principles in government; wherein, however, he afterwards proved very variable and inconfiftant. He oppofed the court alfo in the long parliament which met in November following, and was chofen to impeach Judge Crawley, which he did in a warm and eloquent fpeech, July the 16th, 1641. This fpeech was fo highly applauded, that 20,000 of them were fold in one day. In 1642, he was one of the commiffioners appointed by the parliament to prevent their propofitions of peace to the king at Oxford. In 1643, he was deeply engaged in a defign to reduce the city of London and the tower to the fervice of the king; for which he was tried and condemned, together with Mr Tomkins his brother-in-law, and Mr Chalfoner. The two latter fuffered death; but Mr Waller obtained a reprieve: he was, however, fentenced to fuffer a year's imprifonment,

Wallace
Waller.

ment, and to pay a fine of 10,000*l*. After this, he became particularly attached to Oliver Cromwell, upon whom he wrote a very handsome panegyric. He also wrote a noble poem on the death of that great man.

At the Restoration, he was treated with great civility by Charles II. who always made him one of the party in his diversions at the duke of Buckingham's and other places. He wrote a panegyric upon his majesty's return; which being thought to fall much short of that he had before written on Oliver Cromwell, the king one day asked him raiillery, "How is it, Waller, that you wrote a better encomium on Cromwell than on me?" "May it please your majesty," answered he, "we poets generally succeed best in fiction." He sat in several parliaments after the Restoration, and continued in the full vigour of his genius to the end of his life, his natural vivacity bearing him up, and making his company agreeable to the last. He died of a dropy in 1687, and was interred in the church-yard of Beaconsfield, where a monument is erected to his memory. Mr Waller has been honoured as the most elegant and harmonious versifier of his time, and a great refiner of the English language. The best edition of his works, containing poems, speeches, letters, &c. is that published in quarto by Mr Fenton, in 1730.

WALLIS (Dr John), a celebrated mathematician, was educated at Cambridge; where he became fellow of Queen's college, and continued so till, by his marriage, he vacated his fellowship. In 1640, he received holy orders, and became chaplain to the lady Vere. While he lived in this family, he cultivated the art of deciphering; and it is said, that the elector of Brandenburg, for whom he explained several letters written in ciphers, sent him a gold chain and medal. In 1643 he published, "Truth tried; or, Animadversions on the lord Brooke's treatise called *The nature of Truth*, &c. The next year, he was chosen one of the scribes or secretaries to the assembly of divines at Westminster. Dr Peter Turner, Savilian professor of geometry in Oxford, being ejected by the parliament-visitors in 1649, Mr Wallis was appointed to succeed him in that place. In 1653 he published at Oxford a Grammar of the English Tongue in Latin. In 1655 he entered the lists with Mr Hobbes; and their controversy lasted a considerable time. In 1657 the Doctor published his *Mathematical Works*. Upon the death of Dr Langbaine, he was chosen custos archivorum of the university. After the Restoration he met with great respect, the king himself entertaining a favourable opinion of him on account of some services he had done both to his royal father and himself. He was therefore confirmed in his places, admitted one of the king's chaplains in ordinary, and appointed one of the divines empowered to review the book of common prayer. He complied with the terms of the act of uniformity, and continued a steady conformist till his death. He was one of the first members of the royal society, and corresponded with many learned men. In 1697, the curators of the university press at Oxford thought it for the honour of the university to collect the mathematical works of the Doctor, which had been printed separately, some in Latin, some in English, and published them all together in

the Latin tongue, in 3 vols. folio. He died in 1703. He speaks of himself thus: "It hath been my endeavour all along to act by moderate principles, being willing, whatever side was uppermost, to promote any good design, for the true interest of religion, of learning, and of the public good." Besides the works above-mentioned, he published many others.

WALLOONS, a name for the inhabitants of a considerable part of the Netherlands, viz. Artois, Hainault, Namur, Luxembourg, and part of Flanders and Brabant.

WALSH (William), an English critic and poet, the son of Joseph Walsh, Esq; of Abberley in Worcestershire, was born about the year 1660. He became a gentleman-commoner of Wadham college, Oxford, but left the university without taking a degree. His writings are printed among the works of the Minor Poets, printed in 1749. He was made gentleman of the horse in queen Anne's reign; and died in 1708. He was the friend of Mr Dryden and of Mr Pope; the former of whom esteemed him the best critic then living; and Mr Pope has celebrated his character in the *Essay on Criticism*.

WALNUT-TREE, in botany. See JUGLANS.

WALRUS, in zoology. See TRICHECHUS.

WALSINGHAM, a town of Norfolk, with a market on Fridays, and a fair on Whit-Monday, for horses and pedlar's ware. It is seated not far from the sea; and in former times was famous for its college of canons, and was greatly frequented by pilgrims who went to pay their devotions to the image of the Virgin Mary at the chapel, where there are two fine springs, called the *Virgin Mary's wells*. Not many years ago there were found here 100 urns full of ashes, by a husbandman, which was supposed to be those which the Romans filled with the ashes of the dead. It is 22 miles north-west of Norwich, and 117 north-north-east of London. E. Long. 1. o. N. Lat. 52. 56.

WALSINGHAM (Thomas), an English Benedictine monk of the monastery of St Alban's, about the year 1440. He applied himself to the history and antiquity of his country, in quality of historiographer to the king; and composed the History of King Hen. VI. with other works.

WALSINGHAM (Sir Francis), minister and secretary of state under the reign of queen Elizabeth, and one of the greatest politicians of his time, was descended from a noble and ancient family at Chislehurst. After having made great progress in his studies at Cambridge, he was twice sent ambassador to France, and at his return to England was employed in the most important affairs; became secretary of state, and was one of the commissioners for the trial of Mary queen of Scotland. Sir Francis undoubtedly one of the most refined politicians, and most penetrating statesmen that any age ever produced. He had an admirable talent, both in discovering and managing the secret recesses of the heart. He had his spies in most courts in Christendom, and allowed them a liberal maintenance; for it was his maxim, That knowledge cannot be bought too dear. In 1587 the king of Spain having made vast preparations, which surprised, and kept all Europe in suspense, Walsingham employed his utmost endeavours for the discovery of that important secret; and accordingly procured intelligence from Madrid, that the king

had

Wal-
ling-
ham.

had informed his council of his having dispatched an express to Rome, with a letter written with his own hand to the pope, acquainting him with the true design of his preparations, and begging his blessings upon him; which for some reasons he could not disclose till the return of the courier. The secret being thus lodged with the pope, Walsingham, by means of a Venetian priest, whom he retained at Rome as a spy, got a copy of the original letter, which was stolen out of the pope's cabinet by a gentleman of the bed-chamber, who took the key out of the pope's pocket while he slept. After this, by his dexterous management, he caused the Spaniards bills to be protested at Genoa, which should have supplied them with money for their extraordinary preparations; and by this means he happily retarded this formidable invasion for a whole year. In short, he spent his whole time and faculties in the service of queen Elizabeth; on which account her majesty was heard to say, "That in diligence and sagacity he exceeded her expectations." However, after all his eminent services to his country, this great man gave a remarkable proof at his death, which happened on the 6th of April 1590, how far he preferred the public interest to his own, he being so poor, that excepting his library, which was a very fine one, he had scarcely effects enough to defray the expence of his funeral. His principal works are, 1. *Memoirs and Instructions for the use of Ambassadors*, with his *Letters and Negotiations*. 2. *Political Memoirs*.

WALTON (Bryan), bishop of Chester, a learned English divine, who gained great reputation by his edition of the Polyglot bible, with his *Prolegomena* in the beginning; which is more exact, says father Simon, than any other which had been published on that subject. He died in 1661.

WAMPUM, the money used by the North-American Indians. It is much used in all their treaties as a symbol of friendship. It is made of a shell of a particular species of VENUS.

WAPENTAKE, is all one with what we call a *hundred*; specially used in the north countries beyond the river Trent. The word seems to be of Danish original, and to be so called for this reason: When first this kingdom, or part thereof, was divided into wapentakes, he who was the chief of the wapentake or hundred, and whom we now call a *high constable*, as soon as he entered upon his office, appeared in a field on a certain day on horseback with a pike in his hand, and all the chief men of the hundred met him there with their lances, and touched his pike; which was a sign that they were firmly united to each other by the touching their weapons. But Sir Thomas Smith says, that anciently musters were made of the armour and weapons of the several inhabitants of every wapentake; and from those that could not find sufficient pledges for their good bearing, their weapons were taken away and given to others; from whence he derives the word.

Wal-
ton
Wapenta

W A R.

WAR is a great evil; but it is inevitable, and oftentimes necessary. If he who first reduced to rules the art of all the sciences: his fellow-creatures, had no end in view but to gratify the passions of princes, he was a monster, whom it would have been happy to have smothered at his birth: but if his intention was the defence of persecuted virtue, or the punishment of successful wickedness, to curb ambition, or to oppose the unjust claims of superior power, mankind ought to erect altars to his memory.

War, in the last case, is the most necessary and useful of all the sciences: the various kinds of knowledge which ought to furnish the mind of a soldier are not without great difficulty to be attained. Of most other sciences the principles are fixed, or at least they may be ascertained by the assistance of experience; there needs nothing but diligence to learn them, or a particular turn of mind to practise them. Philosophy, mathematics, architecture, and many others, are all founded upon invariable combinations. Every man, even of a narrow understanding, may remember rules, apply them properly, and sometimes draw just consequences from them: but the study of war is of another kind. Experience can so seldom be referred to rules, that nothing but a mind enlightened by diligent study can make a due application of rules to circumstances.

Most artists may join practice to theory, and make one perfect by the help of the other. The warrior has not always the like assistance: he spends part of his life in forming plans, of which humanity does not suffer him to wish the execution; and when he has an opportunity of judging from experience of the solidity

of his principles, the operations are so rapid, the motions so diversified, the actions so confused, that he has scarcely time for a glimpse of those things which require the most calm and close consideration.

In learning of every kind, theory is the completion; in the study of the military science, it is only the introduction. Many a man, depending on his rules, has found that the marches, the camps, the dispositions, the manœuvres, performed with exact and strict order in the closet, have not only been very difficult, but even impracticable in the field. A disposition good in a mountainous country, would be bad in an open one; a disposition proper for one open country may fail in another, for want of foreseeing that a manœuvre, which in one case may have been the cause of winning a battle, may in another occasion its loss: the circumstances of time and place almost always throw the best constructed systems out of order. It is therefore only by dint of study, and by the contemplation of cases incessantly varied, that the want of practice can be supplied, or action at least made less difficult.

A military man who would be master of his profession, has no hours to lose; in peace, he ought to study with the greatest diligence; in time of war, he will see his principles open themselves of their own accord: his ideas are then more distinct; he acts with clearness and certainty in all cases he has foreseen, and applies his rules to all those which now occur for the first time, and which till then had escaped his thoughts. Who does not know that bravery, courage, and comprehension, are useless, and often fatal, to a military man who wants knowledge of his business? Having no previous
helps

helps from study, it often happens that the braver he is, the more he is liable to mistakes, and the less able to foresee or avoid them.

The science of war branches out into so many particulars; it takes in so many different parts; there are so many reflections necessary to be made, so many circumstances and cases to be brought together; that it is only by a continual application, grounded upon the love of his duty, and an inclination to his profession, that any man can attain it.

To march an army in every sort of country, whether open, woody, or mountainous; to know how to form a camp in all those countries, with which the general must be thoroughly acquainted in order to do it with security; to make a proper disposition for a battle, whether with a view to the posture of the enemy, or to the situation of the country; to foresee events which depend in a manner upon chance; to be capable of making a good retreat on proper occasions; to direct the forages without fatiguing or exposing the troops; to send out detachments with precaution; to conduct the convoys in safety; to know how to canton an army; to establish magazines in places, both safe and within reach of the army, so that it shall never be in want of subsistence; these are the great ends of the military science. The Alexanders of Parma, the Spinolas, the Gustavuses, the Weimars, the Condés, the Turennes, the Montécucullis, the Vendomes, the Marlboroughs, the Eugenes, and all the great men who have gone before us, would never have been the subject of our admiration, if they have neglected this study in any of its branches. It is by courage, genius, and capacity; by having an head always cool, and an eye at once quick and exact; by a nice knowledge of the country, by skill in the choice of officers, and by strict discipline kept up in his army, that a general is enabled to take such just measures as will frustrate the designs of the enemy.

It is commonly thought sufficient for a military man to know how to obey; and it is also supposed that the success of a day cannot be dubious, if a general joins the confidence of the soldiers to all the foregoing qualities.

It is true, that, in cases of perplexity, many generals have in a great measure owed to their own capacity, and the confidence their soldiers have reposed in them, the advantages they have gained over the enemy; but is the officer who loves his duty, and who would make himself master of it, under the less obligation to know what qualifications his station requires? That he ought to have such or such a quality, in such or such a circumstance? that here only bravery is necessary, there only courage? and that he is not always obliged to have both at the same time?

These two virtues, which are often confounded in the same subject, merit a particular distinction; they are not so closely united, but they are often to be found one without the other. Courage seems fittest for a general, and all those who command; bravery more necessary for a soldier, and all who receive orders; bravery is in the blood, courage in the soul; the first is a kind of instinct, the second a virtue; the one is an impulse almost mechanical, the other a noble and sublime conception. A man is brave at a particular time, and according to circumstances; he has courage at all

times, and upon all occasions: bravery is so much the more impetuous as it is less the result of reflection; courage, the more it is the effect of reason, becomes more intrepid. Bravery is inspired by the force of example, infensibility of danger, and the fury of action; courage is infused by the love of our duty, the desire of glory, and zeal for our king and country: courage depends on reason, but bravery on the constitution. Achilles, such as Horace describes him from Homer, implacable, cruel, despising every other right but that of force, presents nothing to the idea but the hardness of a gladiator. But the Roman general, whose death would have produced the ruin of the army, the great Scipio, when covered by the bucklers of three soldiers, to avoid a shower of arrows which the enemy directed against him, approaches in safety the walls he besieged, and standing only a spectator of the action, and contenting himself with giving them orders, exhibits the idea of true courage. Bravery is involuntary, and depends not at all upon ourselves; whereas courage (as Seneca observes) may be taught and acquired by education; but yet nature must sow the first seeds of it. It would be easy to make the difference of these qualities better understood, by running over all the cases in which they make their appearance, were it not for the fear of going too far in so copious a subject. It is said of a magistrate who exposed his life and fortune in defence of the laws, that he has virtue. Cicero, sheltering himself from the hatred of Cataline, undoubtedly wanted bravery, but certainly he had an elevated firmness of mind (which is in reality courage) when he disclosed the conspiracy of that traitor to the senate, and pointed out all his accomplices; or when he pleaded for Deiotarus against Cæsar, his friend and his judge.

Coolness is the effect of courage, which knows its danger, but makes no other use of that knowledge than to give directions with greater certainty: courage is always master of itself, provided against all accidents, and regulated by the present occasions; never confounded by any danger so as to lose sight of the motions of the enemy, or of the means by which he may be most effectually opposed. At the battle of Cannæ, when Gisco seemed to be much astonished at the superiority of the enemy's number, Hannibal answered him coolly, "There is, Gisco, a thing still more surprising, of which you take no notice." Gisco asking him what it was, "It is (replied Hannibal) that in all that great crowd there is not one man whose name is *Gisco*." Plutarch observes, that this coolness of Hannibal greatly animated the Carthaginians, who could not imagine that their general would joke at so important a time, without being certain of overcoming his enemies.

Although bravery and courage are the most essential qualifications of a subordinate officer, yet he should not be deficient in those which are required in a general, and which have been already mentioned; obedience to the orders delivered to him is no longer a virtue than whilst he comprehends and knows the intention of them. War, says a celebrated author, is a business which, like all others, must be learned; it supposes some qualities to be born with us, and demands others which are to be acquired: but since all these qualities must have the original source in genius, a man who proposes war for his profession, should never en-

gaze in it without having consulted his natural bent, or without knowing the particular turn and power of his mind. Ability, whether in a general or an officer, is the effect of his genius, quickened by a natural liking to his business.

But some are by their birth engaged in the profession of arms before time has permitted them to consult their genius and their powers; are these men to quit it if they perceive that they are not endowed with every talent that profession requires? Undoubtedly no; because they may acquire them. Study and application will supply the defect of genius; docility may serve instead of talents, the love of glory be equivalent to a liking for their business, and the virtues of their fathers should always be present to their thoughts. When a man has no ancestors to imitate, he is, as may be said, at liberty to raise a reputation of more or less lustre: by being descended from celebrated ancestors, he is obliged to follow their example, and may often improve upon their virtues. Claudius reproached Cicero with being the first of his race. But you, answered Cicero, are the last of yours. An illustrious descent is oftentimes a burden; if it adds splendour to the man of virtue, it always disgraces him who knows not how to support it.

A quick eye is natural in some, and in them it is the effect of genius; others acquire it by study or experience; he who knows how to command himself, and has courage enough to keep himself cool on the most urgent occasions, has the readiest and quickest eye. A quick hot-headed man, however brave, sees nothing; or if he does, it is confusedly, and generally too late.

It is this quick eye which enables him to judge of an advantageous post, of a manoeuvre to be made, and of a good disposition for the troops, whether with respect to that of the enemy, or to the situation and nature of the country.

There is a quickness of eye which depends upon the enemy, and another independent of him: it depends upon the enemy when he has made such a disposition, that to attack him, another must be made upon the spot which renders his defective and weak in some parts; or when, being advantageously posted, the general obliges him to change his position, by making him fearful of being taken in flank, or being surrounded; or when it is so contrived as to render the troops on the right useless by attacking the left, without their being able to assist it.

It is independent of the enemy, when a commander being at a distance, knows how to take an advantageous position, and how to choose a camp strong by situation; when he sees at once what distances there are upon the right and left of the troops that may prevent their being either molested or surrounded, and observes the posts necessary to be occupied for their safety; when he marches with a detachment, and diligently surveys the ground by which he may retreat if he should be attacked and repulsed by superior forces, taking care that he may not be surrounded, and that the enemy may not be able to oppose to him a front more extensive than his own.

The quick eye is no other than that penetrating genius which let nothing escape it. A general who knows how to unite this quality with perpetual coolness, never is in want of expedients; he will see how

those events, which to any other would be the preface of his own defeat, may end in the overthrow of his enemies.

The army of Cyrus, in the presence of that of Cræsus at Timprea, took a clap of thunder for a bad omen: this impression escaped not the quick eye of Cyrus; but the coolness which on this occasion he knew how to preserve, suggested to him an interpretation which removed his soldiers fears. "My friends," cried he, "heaven declares for us; come on, I hear the sound of victory: Great Jupiter, we follow thee."

The choice of the general officers depends upon this genius, which discovers every thing; they ought to be the right-hand of the general, and as capable of commanding the army as himself.

Whatever good dispositions a general may make, they must prove ineffectual if not seconded by the general officers under his command; he cannot be every where, neither can he foresee all exigencies that may arise. He is obliged to give only general orders; it is therefore the business of those who command under him to know how to take the advantage of a wrong movement of the enemy; to take upon them to attack, or sustain the troops which are engaged; and, as circumstances vary, to make them advance towards the enemy, either to keep him back or to attack him. But still we must except the reserve, which ought never to march without an order from the commander in chief.

But the qualities already mentioned would be useless, if order and discipline were not severely observed: the most numerous and best composed army would soon become little else than a body of rangers, who being only united by the hope of booty, would separate as soon as that motive ceased; and trusting each to his own head, or indulging his own humour, would be cut in pieces party by party: so that, if the general does not keep up subordination (the soul and strength of discipline) his army will be nothing more than a troop of Tartars acting more from the hope of plunder than the desire of glory. What art and what genius is there not requisite to maintain this subordination? Too much severity disgusts the soldier, and renders him mutinous, discourages him and makes him desert; too much indulgence sinks him into idleness, and makes him neglect his duty; licentiousness causes that subordination to seem burdensome, which should never in any degree be given up: he loses that respect, and often that confidence, which he should have with regard to his officer; and indulgence often makes a well-disciplined body become a set of sluggards, who march against their will, and who, on the most pressing emergencies, think only on their own safety.

The ability, foresight, and prudence of a general, gains him the entire confidence of the soldier and officer: the soldier indeed judges but by instinct, and is determined only by the event; but his judgment is not less infallible: that of an officer is equally just, but he is determined only by full conviction; he puts event out of the question, and places his confidence in nothing but courage and prudence. Confidence is again to be acquired by assiduity to those who are subordinate to us, and by supplying their wants before they are complained of; these two motives for confidence afford a plentiful and certain harvest of laurels

rels to the general. M. Luxembourg, M. Turenne, Prince Eugene, Marshal Saxe, and many others, have partly owed the advantages they have gained over their enemies to the confidence of the soldiers, who, loving their general, considered it as their duty to please him, and had no joy in victory but as they shared it with him.

Besides these qualities, which are essential to a general, and which all who would attain that rank ought of course to have, there are still many others necessary to make a great man. A hero is always a good member of the community; he considers humanity as his first duty; he is just, open, and unbiassed; his temper may be fiery, but this ardour is always regulated by prudence: he gives advice with the same openness as he would ask it; and never asks but of those whose experience, which he estimates rather by their actions than their age, makes them capable of giving such as may be trusted; he is haughty only to his enemies, free to his equals, affable to his inferiors, brave without either arrogance or rashness, and easy of access to all.

The general ought to be acquainted with the interests and force of princes, (a science very necessary in judging of the power of princes upon whom war is made, that he may fall sooner upon the country of him who can obstruct his projects, than upon a prince who, by the situation of his dominions and force, can make no opposition). In a word, a general who would merit the title of a great man, ought to unite in himself all civil, military, and political excellence. It is by this that he will easily attain to make war with success: nothing will escape him; he will know without difficulty the genius of every country, and of the nations which compose the enemy's army, the abilities of the generals who command, and the nature of the troops under them. Without these precautions he would never think that he could act upon certain grounds; he knows he may venture a motion with some troops that he would not dare attempt with others that are equally brave. One nation is vehement, fiery, and formidable in the first onset; another is not so hasty, but of more perseverance: with the former, a single instance determines success; with the latter, the action is not so rapid, but the event is less doubtful.

No man is born a general, although he brings into the world with him the seeds of those virtues which makes a great man: Cæsar, Spinaola, Turenne, the great Conde, and some others, shined, even in their earliest years, such qualities as ranked them above other men; they carried within them the principles of those great virtues which they drew forth to action by profound study, and which they brought to perfection by the help of practice: those who came after them, with perhaps fewer natural talents, have by study rendered themselves worthy of being compared to them. Cæsar and all conquerors had this advantage, that they were able to make their own opportunities, and always acted by their own choice. A man may be a good general without being a Marlborough or a Turenne: such geniuses are scarcely seen once in an age; but the more they are raised above the rest of mankind, the more they ought to excite emulation. It is by endeavouring to surpass the intellects of the second rate; it is by striving to equal the most sub-

lime, that the imitation of them is to be attained. This passion in a soldier is neither pride nor presumption; it is virtue: and it is by this only that he can hope to be serviceable to the state, and add to the glory of his king.

How much soever the honour of commanding armies may be fought after, it degrades him who is not worthy of it; this rank, so much desired, borders on the two extremes of glory and ignominy. A military man who labours to make himself capable of commanding, is not to be blamed; his ambition is noble: by studying the art of commanding, he learns that of obeying and of executing. But it is astonishing in the highest degree to see soldiers thinking only on preferment, and neglecting the study of their business. It is perhaps less surprising if we see others, without having been tried, proposing to themselves to command in chief; because such attempts suppose in the projector an absurd temerity, founded on a profound ignorance of the talents he ought to have, and the virtues which he has not. Such boldness is the character of a man whose mind is too narrow to perceive his danger: We should rather approve the timidity that suffers itself to be dejected by terror, since it shows at least that he knows to what hazards he is exposed; both one and the other are blameable: modesty is the only proper quality of a soldier; it gives splendour to virtue, it argues diffidence of himself, and desire of arriving at perfection.

MarJonius, Xerxes's general, proposed himself to the king to command his armies; this conceit of his own talents ought to have been answered by a refusal: the innumerable troops which he led were defeated by a small number of Greeks, and his presumption served but to increase the misfortune of his prince. Cincinnatus, endowed with every quality both of a great man and a great soldier, was holding his plough when the Roman's came to intrust the fate of the republic to him: he set out; and Rome was delivered from her enemies.

The title of general would be less tempting, if proper attention was paid to the qualities it requires, and the duties it imposes; it would then appear a very honourable, but painful burden. The most firm and intrepid genius might be discouraged, merely by thinking that on the conduct of a general depends the fate of a state, the glory of his prince's arms, and his own reputation.

But yet the reward that follows such irksome labours ought to animate men to undertake them. Obstacles, however numerous they may be, are not insurmountable, since so many great men have got the better of them: difficulties should stir up a soldier's emulation, but should never terrify him; he should endeavour to copy such great originals, though he should not be able to equal them.

This treatise is divided into four parts.

In the first are mentioned all the greater operations of a campaign; and the means of executing those operations, in any kind of country, are endeavoured to be laid down.

In the second, the precautions that are to be taken to attack the enemy in all the forementioned operations, are considered.

PART I. Of the GREATER OPERATIONS in DEFENSIVE WAR.

SECT. I. *Of the Knowledge of a Country.*

A CAMPAIGN of which the plan is well formed, and the dispositions well concerted, may nevertheless prove unsuccessful, if the general, to whose direction they are intrusted, hath not a thorough knowledge of the country in which they are to be carried into execution. The marches, camps, convoys, forages, detachments, in short the most important operations, will be performed with impropriety, if this knowledge is not previously acquired: events are often determined by it.

There is one knowledge of a country, which for an officer to be without, should be considered as a reproach; that of the situation of cities, towns, villages, forests, streams, rivers, which is to be acquired by studying of geographical maps. There is another branch of knowledge yet more particular, such as, of the passes, or the boundaries of the country, the situation, the nature of the ground, whether it is plain, or divided by hollows, rivulets, hills, &c. which is to be acquired by the assistance of topographical maps. In the study of these last, care must be taken, not blindly to follow the marks they lay down. It very seldom happens, that topographical maps are perfectly exact: for, besides the many circumstances which may sometimes in a year alter a large extent of country, they seldom take notice of fords, bridges over the small rivulets, small hills, and hollows of little importance; neither can they mark whatever may be occasioned by recent inundations and disruptions of the earth: whereas any of these unforeseen circumstances may prove an obstruction to a great design, either by retarding the march of an army, preventing a column of troops from advancing, or leaving the enemy in possession of some passes from which he might have been driven.

It is nevertheless impossible for a map to explain every particular: for example, an hollow way may be marked, but its depth will still remain unknown; neither can it shew whether the ascent and descent of it be easy or difficult. A general, studious to avoid the imputation of negligence, ought, before he engages in an enterprise, to make himself acquainted with every particular relating to the country, and by that means make up for the deficiencies of the maps. In short, if he is desirous of fixing a camp in a position strong by situation, but unacquainted how that is to be done, or in what manner the wings can be supported, he should then get information whether there is any river by which the camp may be covered, whether this river can be passed easily, and what is the nature of its banks.

In order to avoid the errors into which a general may be drawn by the maps, the safest method is to apply to the inhabitants of the country, and go over it with the most intelligent of them, and remark every obstacle, however trifling in may appear.

For marching with greater security, a general ought to form a company of guides of the peasants,

be assured of their fidelity, and attach them to him by all possible methods, particularly by unbounded liberality. It is by money only that truly spies and faithful guides can be secured; the latter are less expensive, but full as necessary as the former. Parsimony should be avoided in war; for, as Vegetius observes, money should never be spared when expence is necessary to secure possession. In proportion as an army advances into a country, great care must be taken to change the guides.

The command of this company should be given to an intelligent man, who should be perfectly acquainted with every thing relating to the country, and who should also be fully able to answer any objections started by the general or officer that accompanies him. This company of guides will be capable of informing the general of whatever may have escaped his observation, of directing him in his inquiries, by which means his discoveries will always be to be depended upon. By this manner of proceeding, neither will the position, or the distance of one place from another, nor the situation of any particular city, town, or village, nor any circumstance be unknown to a general who joins their information to what he himself already knows: he will be informed of all the pathways, of the different roads leading into the country, and what number of them terminate at the same point; he will judge what number of men, either horse or foot, can march abreast, whether the enemy can prevent his pursuing his intended route, by taking the field, and to what distance he will be able to march in safety.

The general should send out detachments along with some of these guides to examine the streams which cross the country, whether or no their mouths are at a distance, into what river they empty themselves, from whence they take their source, whether they may be easily forded, if their banks are steep or sloping, marshy or covered with bushes; other detachments should be employed in examining the woods, in order to find out whether troops can pass through them or not.

A general ought himself to examine into the truth of the reports made to him by these small detachments, or send out others more considerable under the command of general officers: however certain a general may be of the fidelity of his spies and guides, yet he should not always rely upon their reports: mistrust, which in general is accounted a vice, may almost be esteemed a virtue in the business of war.

Furnished with these lights, a general can allot the easiest road to the artillery and baggage, the shortest to the infantry, and longest to the cavalry: he can at once judge, from the nature of the ground, into how many columns the army can be divided in order to expedite the march, and what dispositions will be necessary for the columns with regard to the enemy's position.

By the knowledge of the country, a general is informed of what camps the enemy doth or can occupy, and of those necessary to be taken to oppose his de-

signs;

signs; whether the enemy's detachments can easily approach, or how he can himself advance towards him, without being discovered; if there is forage in the neighbourhood of the enemy's camp, or whether he is obliged to draw it from a distance; where he hath fixed his magazines, and whether an attempt to carry them off is practicable or not; in what manner his quarters are disposed, and which of them is most exposed; what distance there is between himself and the enemy; where the enemy hath established posts, and which those are that himself ought to occupy with regard to the situation of his own camp and quarters, and those belonging to the enemy; which is the properest road for the detachments and the patrols to keep, in order to gain intelligence; and lastly, with what degree of ease the enemy can attack the army on its march, and whether in front or flank. This knowledge is essential to a general in every kind of country; but in a woody or mountainous country, it would become more particularly dangerous, and even impossible for him to march an army, if unacquainted with it.

By the maps, a general will know whether there be forests in a country: but if he does not endeavour to get a more particular information, he will be unacquainted with the nature of them; whether they are boggy, smooth, or rugged; and consequently, whether it be possible for the troops, artillery, and baggage, to pass through them.

In 1702, the duke of Burgundy, being desirous to attack the enemy who were behind Cleves, but not being perfectly acquainted with the forest in his front, he detached the marquis d'Alegre with 500 grenadiers, and 800 horse, to see if it was not possible to find some passage through it. M. d'Alegre met with a defile which was occupied by the enemy: he attacked and forced it; but being advanced beyond it, found it was not possible to proceed farther, by reason of the great number of defiles that succeeded to each other: he thereupon turned back, sent, and had another passage surveyed, where there were found still greater obstacles. He gave an account of this to the duke of Burgundy, who, not choosing to miss the opportunity of attacking the enemy, sent him out again with a larger detachment, that he might examine whether, by keeping along the side of the forest, it would not be practicable for him to march up to them by way of the heaths of Mook, on the side of Grave and Nimeguen. The marquis d'Alegre discovered a defile which led to these heaths: he took possession of it, and sent notice thereof to the duke of Burgundy; who ordered the army to advance, obliged the enemy to send their infantry into Nimeguen, and cannonaded their cavalry which had taken post on the glaciis, but were unable to maintain it; and the consequence was, that the enemy sustained a great loss in men, artillery, waggons, and baggage.

This example tends to prove, that maps are not always to be relied on. There can be no reason to doubt that the duke of Burgundy was furnished with the most exact; but yet it is probable that he might not have succeeded in this enterprise, if he had neglected sending M. d'Alegre to survey the passes, and examine two, before he proceeded to that through which he marched.

The following is a general rule: That it is upon

the ground, and not upon maps, that the roads thro' which an army is to march must be examined, as well as the situation of places where camps are to be fixed, and fields of battle chosen. An army should never move before ways are opened for every column: with regard to a detachment it is different, as there may arise circumstances which will prevent the general from foreseeing what road it may take. The command of a detachment should always be given to an intelligent officer, and one who has made his business his only study; who hath been particularly careful to acquire a knowledge of the country, and of whose genius the general should entertain no doubt. A particular choice stirs up emulation in young men, and induces them to exert their utmost endeavours to deserve so distinguishing a mark of approbation.

Into how many mistakes have even the greatest generals fallen, by not being thoroughly acquainted with a country, and by suffering themselves to be guided by general notions? M. de Feuquieres cites many examples of great enterprises which have miscarried by it.

Toward the end of the year 1673, when a considerable body of infantry, with only few cavalry, was on its return from Holland, under the conduct of M. de Luxemburg, the prince of Orange having assembled the whole force of the Dutch and the Spaniards (under his command) came upon the Maese, with an intention to fight M. de Luxemburg between Maelricht and Charleroy. This march made it necessary for the court to send an order to M. de Schomberg to assemble all the cavalry that were in Hainault and Flanders, and immediately join M. de Luxemburg, who was greatly inferior to the prince of Orange in cavalry. The prince's aim then should have been to prevent the two generals from joining, and to have fought one or other of them before their junction. The prince's being unacquainted with the country, made him mistake for real the feints made by M. de Luxemburg, whilst he was upon the river Ourte; as if his intention was to march by way of the Condros and the Ardennes, in order to gain Sedan and the Mezuris. The prince of Orange drew near Huy and Namur; and by that means was at such a distance from the high-road, that M. de Schomberg had an opportunity of advancing with his cavalry to Tongres; at the same time that M. de Luxemburg, by a forced march, passed the Maese at Maelricht, and arrived at Tongres, where the junction of the two armies was effected without any accident.

If the prince of Orange had made only two reflections upon the nature of the country, he would have avoided the mistake he fell into; the first of which is, that scarcely any body can be ignorant that the Condros and the Ardennes are sterile and mountainous countries; from whence it is evident, that M. de Luxemburg could not have subsisted his army, especially in the month of December: the roads in those parts, very bad in the summer, are almost impassable during the winter; consequently the carriages could not have passed but with the utmost difficulty.

The second reflection is, that if M. de Luxemburg had actually designed to pass through the Ardennes, why did M. de Schomberg advance towards Tongres, and so expose himself to the danger of being beaten, without a possibility of receiving help from M. de

Luxemb.

Luxemburg, who was on the other side of the Maefe? If the prince of Orange had had a thorough knowledge of the country through which M. de Luxemburg pretended he would pass, he would soon have perceived that it was only to throw him into a perplexing uncertainty with regard to the road which the enemy's general should naturally take: in a word, he would not have remained a moment in doubt on the part he had to act.

By this, then, it appears, that the prince ought to have continued on the side of Liege; by which position he would have stopped M. de Schomberg, who would have scarcely dared to advance to Tongres, nor would M. de Luxemburg have attempted the passage of the Maefe at Maastricht: by this means, the junction would have been prevented; or, if either of the two armies had advanced, the prince could have attacked and beaten it; neither would it have been in the power of the other to have assisted it.

It is certain, that a thorough knowledge of the country would have induced the prince of Orange to have remained on the other side of Liege; by which position the junction of M. de Schomberg and M. de Luxemburg would have been impossible: this last would then have been, in a manner, compelled to continue his march by the Condros and the Ardennes; and the prince of Orange, without losing a man of his own army, would have made M. de Luxemburg lose a great number of his, who would have been unable to have resisted both hunger and cold.

With the company of guides, and an exact knowledge of the country, a general will be enabled to undertake an enterprise, that another with double the number of troops durst not think of attempting. These precautions will furnish him with stratagems, oftentimes more efficacious than force and courage: under the appearance of flight, a general will often get possession of an advantageous post, and decoy the enemy into one that may prove his undoing.

It hath frequently happened, and will continue to do so, that a general who knows how to take advantage of the knowledge of the country, although inferior in point of force, may change a defensive into an offensive war. In 1671, M. de Créqui, who began the campaign on the defensive, ended it with obliging the duke of Lorraine to pass the Rhine: that prince dispersed his army, and then M. de Créqui formed the siege of Fribourg.

The knowledge of a country is still more essential in retreats: there is more art and more precaution required in a retreat, than in any other action; that operation is the conclusion of all preceding ones. If a general, obliged to retreat precipitately, hath but a superficial knowledge of the country, how will he be able to reassemble his troops, reestablish order, or march with any degree of security?

Xenophon's retreat with the ten thousand Greeks, is one of the most useful lessons a commander can study: in that undertaking were united the virtues of a consummate general, and the most intrepid courage of a soldier; and in particular it exhibits the most profound knowledge of the country.

The knowledge of a country is as necessary for a private officer as for the commander in chief, because he is to execute in part what the general performs

with all the troops. When an officer, to whose conduct an expedition is intrusted, joins this knowledge, one of the chief branches of military science, to practice and experience, he will with so much the greater ease comprehend and execute the general's intention and plan; and he will be also enabled to take the proper measures for success: if, on the contrary, he begins a march, without being acquainted with the country, his mind misgiving him, will increase the danger, by the very means he takes to avoid it: he will suppose it in places where there is nothing to be feared, and often fall into it where he was least apprehensive of it.

The general who commands in the cantonments and winter quarters, and each officer who commands a particular quarter, will never be able to take proper measures if they are unacquainted with the country: they will be unable to preserve a proper strength when separated, or to assemble without difficulty on the first order; and for want of knowing the posts which it is proper to guard, they will occupy such as are unnecessary, and leave those defences that are most liable to be attacked; the troops will be greatly fatigued by increasing the number of posts without occasion, by superfluous or too numerous detachments or patrols. In a word, whatever precautions are taken within the quarters will never be in security, if the country round about them is not perfectly known.

Unless a general demolishes those bridges which from their distance he cannot guard; if he neglects getting possession of all the passes, occupying the country that is between him and the enemy with detachments, and cutting off all communication with the enemy and his camp, he will be liable to be surprised in it. A general should always know whether there are any rivers between his camp, his quarters, and the enemy's; he should constantly have detachments upon those rivers, to prevent the enemy from repairing the bridges or passing the fords; he should cause the woods to be carefully scoured; he should occupy the avenues and the defiles, and know at what place the roads begin, and where they meet: if any of these precautions are neglected, a general can never remain quiet, but will always lie open to some surprise.

SECT. II. *Of the Preparations before taking the Field, and the March of an Army on leaving its Quarters to go into Cantonments.*

THE time for an army to come out of winter-quarters, is always regulated by the plan which the general has formed for the ensuing campaign. It leaves them very early, when they are at a distance from the country where the war is to be carried on; but later, if, by their situation, the operations of the campaign can be commenced after having made two or three marches; but whether by the situation of the quarters the army is enabled to enter immediately on the campaign, or whether it must be first of all cantoned, the magazines should be so situated as to be always within reach, especially in that early season of the year, when there can be no forage upon the ground, and consequently the cavalry must be supplied out of the magazines. The magazines ought to be distributed about in different parts, that the troops may have less way to go for their forage. The general is to issue his orders

ders to the intendant of the army for whatever regards the magazines, and to mark those places to him where he would have them established; and, for the greater security of these places, there must be troops posted in them, the roads should be good, and the communication well guarded, by which means the convoys will arrive in safety.

The distribution of the magazines should be regulated by the movements which the general foresees the army will make on leaving its quarters, supposing it leaves them when there is only dry forage; but if the army is in an enemy's country, and there is forage upon the ground, it is certainly better to reserve the magazines entire, by which not only great trouble will be avoided in transporting the forage, but also a great expence saved to the government.

Of what nature soever the country may be (an enemy's country is supposed) it should be foraged in front, as much as possible, in order to reserve that which is in the rear, that, when the campaign is over, it may be found laid up in the barns; if this precaution is not attended to, the army will be destitute of forage at its return, and will of course be obliged to draw it from home, and consume those magazines which were before spared; consequently there will be nothing saved, the expence will only have been deferred, but it will be increased by transporting the forage from the magazines to the army.

The forming of the magazines should never be delayed till the time for opening the campaign approaches. The intendant, pursuant to the general's order, should lay in the provisions during the winter, and distribute them in the frontier towns, by which means they can easily be transported to whatever place the general shall order. By these precautions, the general will not only avoid the inconvenience of being obliged to wait till there is forage upon the ground, but he will be enabled to be first in the field.

The same precautions should also be taken with respect to the artillery; whether for that wanted for a siege, if it is intended to open the campaign by that operation; or whether for that which is necessary in the course of a campaign. It should be assembled upon the glacis of the frontier towns, or rather upon that of the conquered places: the more it is within reach of readily joining, the sooner the operations will be commenced.

From prudence in the execution of these dispositions, as well for the magazines and for the artillery, as for every thing that is necessary to an army, it follows, that a general hath often formed a siege, or at least invested a place, and completed his lines of circumvallation, before the enemy could be in a condition of coming out of his quarters: he will likewise have made many marches, and will have possessed himself of advantageous posts, without the enemy having it in his power to oppose him.

The success of the general's design is ascertained by his own forecast, and the dispatch with which his orders are executed; negligence and sloth are always productive of miscarriages.

Here would be the proper place to point out the order which an army should observe in its march to invest a town, and to mention the precautions necessary to be taken for doing it with security; but this would

be only repeating what has been already said by the marshal de Vauban, with regard to this grand operation. What could be said here would not in the least add to the depth and wisdom of his instructions: the reader is therefore referred to the writings of that great man, as this branch of military science doth not fall within the design of this work.

A general should observe, that, in order to make an army come out of its quarters, and cause it to be cantoned within a march of the country where he designs to commence the operations, he must make all the troops leave their quarters together; assemble them in many bodies, in different frontier towns; proportion the marching days to the distance of the quarters and the rendezvous that shall have been appointed for them, that they may arrive on the day appointed, and that from thence they may march in a body to the place where they are to canton.

All the bodies march, either in the number of columns that the situation of the country will allow, and arrive at the cantonment together; or else they march separately, and arrive on different days: but, in either of these cases, the cantonments for each regiment ought to have been marked out; and, if possible, forage for at least three or four days distributed to each quarter.

In the marching-orders which are sent to each commander, the situation and name of the place where each regiment is to canton, should be carefully expressed; whether on the right, the left, or in the centre: the discipline to be there observed, the place where to go and receive orders, and that where to receive forage, should also be particularly specified.

Troops, when upon a march, should always observe the most exact discipline; and never be suffered to advance, but in the same order, and with the same precaution, as if they were in danger of being molested or attacked.

Wherever an army is cantoned, it is generally in an enemy's country; therefore, for the greater security of the cantonments, there should at least be one place that may serve for a support. In 1746, Brussels was the centre of the cantonments of M. Saxe's army. In 1747, his quarters were supplied by Anvers on the left, Malines and Louvain supported the centre, and Namur the right. If no place of this sort can be found, the army must then march out together and encamp, instead of going into cantonments.

As the cantonments are properly nothing more than a halting place, where the troops are to remain till the season permits them to take the field, till the proper quantity of forage is collected, or till the necessary preparations for the intended operations are completed, they should necessarily be more connected than the winter-quarters. But as soon as the weather permits, and all the necessary preparations which should have been forwarded during the winter are finished, there is then no time to be lost; for an army will always find its advantage in encamping early, getting the start of the enemy as much as it possibly can, and beginning the campaign, no matter by what operations, before the enemy can have time to assemble.

The greatest generals of former times have constantly adhered to this rule; and, in our times, it hath always been followed by marshal Saxe. The canton-

ment.

ment of his army under Brussels in 1746, and the famous march he made in 1748 to invest Maëstricht on leaving his quarters, are examples which ought to serve as models; but in all these cases, the varying of circumstances must be attended to.

If any particular column, upon the march, presents its flank to any of the enemy's towns, although it is indispensably necessary for every column to observe all possible order and discipline on the march, yet this column is more particularly obliged to it; necessity makes it become a duty. But that it should not be too much exposed, some hussars ought to be appointed to march upon its flank, who should also be ordered to advance till they come within sight of those towns. This column, whether consisting of infantry or cavalry, must detach some troops to sustain the hussars, in case they should be attacked and repulsed. By posting these detachments upon the flank, the enemy will be kept at a distance from the column, and the hussars will be also sustained.

SECT. III. *The March of an Army in an open Country.*

If, according to the observation of Vegetius, an army is in a more dangerous situation upon a march than when it is drawn up in order of battle, because a soldier, not seeing his enemy, is not so much upon his guard, there is consequently a greater degree of precaution required in a general, that he may not be surprised by an unexpected attack, or fall into ambuscades, the likelihood of which should always make him proceed with caution.

It is upon a thorough knowledge of the country which is the seat of war, that a general should direct the march of armies; that he should concert the measures for conducting them in safety; and that he will be enabled to foresee the enemy's motions.

There are but three sorts of countries which may become the theatre of war, an open country divided by rivers, a woody, or a mountainous one. The dispositions for a march must be varied as the situations of places are different. Although the face of an open country is sometimes interrupted by woods or hollows, there are nevertheless fewer precautions necessary, because it exposes, or at least does not greatly conceal, the enemy's manoeuvres from the general. In a mountainous country the danger becomes more considerable, because those very obstacles which serve to impede the progress of an army may prove to many resources to the enemy, who can march without being seen, and lay snares at almost every step they take.

When an army is in an open country, the general may take whatever road he thinks most convenient, without being under a necessity of keeping the beaten road. If he chooses to march across the country, it may be done by cutting down the hedges, filling up the ditches, levelling the ridges, and filling up the hollow ways, thereby rendering their ascent or descent easy, and by building bridges over the streams and rivulets which divide the country. But nevertheless it is very imprudent for a general to suppose himself entirely free from danger upon a march; for the consequences of self-security are generally fatal. The effects of negligence in any military operation are pernicious, but more particularly so upon a march; and although a

general should never fear his enemy when in presence of him, he should nevertheless always apprehend the worst from him when he is out of his sight.

The number of columns in which an army can march in an open country is arbitrary, whilst it is advancing, and the enemy at too great a distance to attack or annoy it upon its march. But if, on the contrary, the enemy is near at hand, and there is a possibility of his attacking the army, it should then be disposed after such a manner, as to form in order of battle in a very short time, and to be able to take a favourable position for action upon the first signal.

The ill success of the French at the battle of Ramillies may perhaps be in some measure attributed to the neglect of this precaution, as it is certain that the French general preserved his original position, notwithstanding the Duke of Marlborough changed his.

If the army presents its flank to the enemy, the dispositions, without considering the probability of its being attacked, should be changed; for an army upon a march ought to be always prepared against any accident that may happen.

A general should never cause an army to move without having previously considered and examined the intended march of it, nor without a thorough knowledge of the enemy's position, and where he is, or without knowing particularly the ground intended to encamp on. An army ought never to move but with some design, either to seize on some advantageous post, to prevent an intended march of the enemy's, to draw him into a disadvantageous situation, to deprive him of subsistence, or to procure some for itself.

This maxim being established, let it be supposed, that a general would cause his army to march, and the enemy's distance to be also such as to secure him from any danger of attacks; the general hath it in his power to open four, six, or eight roads, in proportion to the number of the troops under his command: for the more number of columns, the less is the body of troops contained in each; consequently there will be less confusion, and the sooner will the army arrive at its destined camp.

The general having nothing to fear from the enemy, who, as hath been just supposed, is at a distance, orders the army to march in six columns; it seems probable he would cause it to be executed by the following dispositions, of which, however, only a general idea can be formed, the whole being dependent upon particular circumstances.

Before the march is planned, and the number of columns determined upon in which the army is to march, notwithstanding the general is acquainted with the country, he should send out a detachment some days before, to reconnoitre the intended route of the army, as well as the camp it is to occupy. This detachment is to be commanded by the officers of the day appointed for its setting out: they must have staff-officers and guides with them, to conduct and to inform them of the nature of whatever may prove an obstacle, of the places where the roads begin, and those where they terminate: they should also have labourers with them, to mend the ways, enlarge the roads, and make new ones, if necessary; to cut down the hedges, fill up the ditches, level the ridges of the hollows, and build or repair bridges.

When

Plan of the March of an Army in Six Columns.

Scale of $\frac{1}{2}$ a League.*A. Bell Sculp.*

When the general commanding this detachment is ready to enter the different ways through which the army is to follow, he will divide his detachment into as many separate bodies as the army is to be divided into upon its march: if into four, the major-general takes the command of one, the brigadier of another, the colonel of the third, and himself will remain at the head of the fourth. This division being thus made, he will distribute staff-officers, guides, and labourers, to each detachment, with orders to meet again at the same place from whence they separated.

Each of these detachments should advance to the extremities of the woods, if they meet with any, and of the roads leading to the camp intended to be occupied: the commanding and staff-officers will then advance with an escort to reconnoitre its situation, and will leave part of their men in ambuscade in the woods, or concealed behind some heights, or in some hollows. The knowledge of the situation of the camp being attained, each detachment will return by the road it came; but first, the commanding officer of each detachment will make a report to the general of the roads they have passed, what discoveries they have made, and, in short, will give him a particular detail of every thing they have met with on their way, whether woods, villages, hollows, bridges, and of every thing they have done to render the road easy for the column that is to pass through it. This detachment being assembled at the place appointed for meeting, will take the road to the camp, where being arrived, the lieutenant-general will make his report to the commander in chief of the army.

With these precautions the army may not only advance in safety, but the roads also for every column having been reconnoitred and repaired, no accident can happen to retard the march of the army.

The general must take care to have detachments of hussars or dragoons always in the front and upon the flanks, to observe and clear the march of the army; neither should a general suppose himself to be in an entire security from the distance of the enemy: but whilst he sees all clear before him, it would show great weakness for him to be apprehensive of a surprise, especially when every necessary precaution for avoiding it hath been taken. It is certainly a mark of prudence to take precautions; but multiplying them without cause is an undoubted sign of fear and anxiety.

It is proper to make the army march, as near as possible, in the same order in which it is to encamp; by which means the troops may enter the camp without confusion. The army being supposed to march in six columns, the infantry will form three, the artillery and baggage the fourth; the cavalry, with the remainder of the corps of hussars that are not detached, and the dragoons, the two last upon the flanks; so that the army, on its march, will be in the following disposition: The column upon the right will consist of cavalry, the one adjoining to it of infantry, and that which comes next will be formed by the artillery and baggage; then two columns of infantry, and the sixth closing, the left will be composed of cavalry. It is to be observed, that, if the baggage-waggons belonging to the army form too long a row, some of them may be sent into the rear of the columns of infantry, with express orders to the officers to make them march in the column.

There should be an advanced and a rear guard to each column, formed from the troops of which the column is composed; there should be also detachments of light horse upon the flanks of the cavalry, in order to keep off any of the enemy's parties that might advance to annoy the army upon its march. The rear-guard to the column of baggage should consist of infantry, cavalry, or dragoons, besides the escort always appointed for it. The general officers who are at the head of the two columns of cavalry, should not march too fast, lest they should get too far advanced before the infantry; a matter always to be avoided. The march of an army being disposed after this manner, every column will enter the camp at the same time, and find itself opposite to its ground. See Plate CCLXXXVIII.

If, by the enemy's position, although at a distance, the army should, on its march, present a flank to the enemy, without fearing its being attacked; yet as the enemy may have stolen one or two marches, as hath happened on many occasions, there must be only two columns of infantry placed in the centre. The third must be placed upon that flank which the army presents to the enemy; so that the army will find itself disposed upon its march after the following manner: Supposing it is the right which presents the flank to the enemy, the first column will consist of infantry, the second of cavalry, the third of artillery, the fourth and fifth of infantry, and the sixth of cavalry. The baggage will then be distributed to the three columns upon the left; so that neither the two columns upon the right, or the artillery, will have the least embarrassment, in case an action ensues. The same disposition must be made upon the left, if it is that which presents the flank. Particular care must be taken that the artillery have orders, supposing the enemy advancing in full force to attack, to transport itself to the column of infantry, and to divide itself along the front, when it shall be in order of battle, and to keep up a constant fire, in order to give the general time to make such dispositions as he shall find necessary.

The column of cavalry should be divided into two, and be posted upon the flanks of the infantry that is drawn up in the face of the enemy; the other columns must follow the orders which have been delivered to them, and execute them with the utmost dispatch.

If it appears, either from the proximity or position of the enemy, that the army is liable to be attacked in front, the disposition for the march should be in the same order as the army is to form in for action: the artillery must then be distributed among the columns of infantry; so that, following the divisions where it is placed, the brigades will find themselves spread over the front of the first line. In this case, the infantry will form four columns, which will march in the centre of the two columns of cavalry upon their flanks; so that the head of each column, as far as the centre, when placing itself in order of battle, shall make the first line, and the remainder, from the centre downward, the second; and the reserve which follows shall form itself behind the other two lines.

It is necessary that an army disposed after this manner, should have orders to draw itself into order of battle on the very first signal, which should be a discharge of two or three pieces of cannon. The signal

being given, the first and second lines, and the reserve, will find themselves formed in a very short time. If, from the proximity and position of the enemy, and the facility with which he can attack, the general hath reason to imagine he will do it, the heavy baggage, with a good guard and escort, ought to be removed into the rear.

On this occasion the *campement* (A) should not be far before the army, the escort should be increased, and some detachments of light horse should march in front to cover it, and also to make observation at a distance. The remainder of the body of light horse shall continue upon the flanks of the army sustained by dragoons, who, on the signal being given, shall immediately go and form themselves in the place assigned to them during the action.

On the first sight of the enemy the *campement* should retire; for when fighting becomes necessary, all thought of encamping must be laid aside; but the escort shall put itself in order of battle, and the light horse shall approach the enemy as near as possible, in order to reconnoitre his disposition and strength. The officer commanding them will immediately send a report of the discoveries he hath made to the commander in chief, who on every occasion should be in the front, and even a little advanced, to survey the nature of the ground; it being very certain, that in these cases a man can much better rely upon his own than upon the judgment of others. This was marshal Saxe's method; particularly when he was apprehensive of being attacked upon a march, or had himself an intention of attacking. In proportion as the enemy shall advance, the escort of the *campement* must retire in good order; at the same time not neglecting the opportunity, if it offers, of harassing the enemy's advanced guard, so as to retard his march, and give more time for the army to form in order of battle, and to the general to make such dispositions as he shall judge necessary: after which, the escort having amused the enemy, or caused him to slacken the briskness of his march, must retire in good order; and when it shall be near the body of the army, each body shall return to its own brigade.

If, from his knowledge of the country, although an open one, the general knows there are any thickets, hollows, or heights, either on the right or the left, and that this spot may prove favourable to the enemy, he should try to possess himself of it. If that attempt is not practicable, as the enemy will undoubtedly take advantage of it, and post infantry either at these thickets or heights, the general must place a brigade of infantry at the head of each column of cavalry, which shall mix by platoons with that line of cavalry when formed in order of battle. This disposition was made by M. de Turenne at the action of Sinzheim, and at the battle of Enzheim.

If, by the situation of the country, the flanks cannot be sheltered either by an hollow, a morass, a river,

a town, or a village, the hussars and dragoons must be posted upon the wings, but sidewise, so as to be able to take the enemy in flank when he shall come down to charge the first line, or at least to keep back his second: these hussars and dragoons should be sustained by the infantry of the light troops belonging to the army. If the right can be formed next a village, and the left next an hollow, some infantry and artillery must be posted there: if there is only the right or the left that can be sheltered, that which cannot must be properly sustained; and the same disposition must be observed that hath been just now mentioned, with regard to an army whose flanks cannot be covered.

If, on leaving the camp, the army presents a flank to the enemy, who may have it in his power to attack it on the march, it must then march but in two or three columns at most. Each column should be disposed after such a manner, that by a motion to the right or to the left, according to the wing that is liable to be attacked, each battalion or squadron may find itself formed in order of battle before the enemy.

The advanced guard should be composed of light horse, sustained by dragoons; the rear-guard of cavalry sustained by infantry: there should be also some light horse upon the flanks of the cavalry, and some pieces of cannon with the infantry. The artillery should be distributed by brigades in the column of infantry nearest to the enemy; so that, performing the same movement as the troops, it may find itself placed in the front of the first line, ready to fire on the first order. The number of three columns is given to the army, in order that the first and second lines and the reserve shall be formed at the same time, which cannot be done if the army marches only in two columns: for troops must then be taken from these two lines in order to form the reserve, which would require a considerable time, and consequently retard the dispositions; whereas this reserve, forming the third column, is separated from the main body, and in a condition to act with readiness, according to the orders it shall have received. As the baggage, in this manner of marching, must necessarily be an embarrassment, it must be sent into the rear under a good escort, with orders to join the next day at the new camp.

It is necessary to observe, that every different species of troops should be placed in that part where it is to fight; consequently the two columns which are to form the two lines when the army shall be in order of battle, ought to be composed of cavalry and infantry; so that when the columns shall make a motion to the right from the left, the infantry may be placed in the centre, and the cavalry upon the wings, unless the nature of the country should make another disposition necessary: then the general should regulate his motions according to the situation of the country, and give such orders as will enable the troops to act with the greatest facility.

Sect.

(A) This is a French term, for which we have not a synonyme equally expressive in the English language. It is used to denote a certain number of troops, who proportion their time of setting out before the army, by the distance or proximity of the enemy, in order to trace or mark out the camp. For this purpose, a quarter-master and a trooper is draughted from every troop of every regiment of horse; and a serjeant and a corporal, in like manner, from every regiment of infantry, furnished with ropes and pickets, to lay out the ground for the tents and the intervals; so that every regiment will, on its arrival, find its ground properly marked out. A field-officer of every regiment also marches with the *campement*, besides the officers of each corps, who command the detachments.

SECT. IV. *The March of an Army in a mountainous and woody Country.*

If the situation of the places in a mountainous country furnishes a general with a greater variety of expedients to conceal his dispositions, it also renders more precautions, and a greater degree of knowledge, necessary to avoid being surprised. If these kind of countries, on the one hand, present greater advantages for the concealment of marches, they also, on the other, offer many difficulties in the transporting of the provisions and the artillery, and require a greater degree of vigilance for the safety of the magazines and the preservation of the communications with the frontier towns.

The general ought to dispose the march of the army according to the situation of the country: he should carefully guard against surprises, whether by night or by day; make himself fore of the passes, and turn them to advantage against the enemy; in a word, he must not overlook any one circumstance, and he should contrive to make even the obstacles themselves turn to advantage.

It is to be feared, that in mountainous countries, in roads that cannot be enlarged, the troops pressed too close together will not be able to move but with great difficulty; and as they will embarrass each other, the front, the rear-guard, and the flanks, must be equally secured; the columns must be unbroken and close, that there be no distance left between them; and halting should be particularly avoided, as that is a circumstance by which an army is most fatigued.

It is again dangerous, as the commentator upon Orosius observes, when troops find themselves straitened of room in a narrow road, for the general, in order to enable them to move with greater ease, to lengthen the columns too much: from whence would arise two inconveniences; the first of which is, that the columns would be weakened; and that in case of a surprise it would not be difficult for the enemy to separate them entirely, and it would also be impossible for them to rally; in the second place, these columns thus lengthened, in going round a mountain and descending into a valley, would take up a prodigious extent; from whence it hath often happened, that the windings of the road hiding the middle of the column, those who march in the front-rank can see only those who are in the last, and retard their march, because that, being deceived by distance, they will be scarcely able to distinguish whether they advance or whether they are halted.

In order to avoid these inconveniences, it is not barely sufficient for a general to have a thorough knowledge of the country: he ought immediately to inform himself of every particular, however minute, relating to it; he should take the same precautions which have been pointed out as necessary for a march in an open country, and send out a detachment, such as hath been supposed in the foregoing section. This detachment will examine the narrow passes, survey and sound the fords, run round the windings of the mountains; and if there are many roads, it will find out which is the most practicable, and that through which the army, the artillery, and baggage, can pass with the greatest ease; what streams cross it, and whether there are

bridges over them: it will examine whether they are sufficiently strong, and repair them, or build new ones. It often happens in a mountainous country, that the road which would be very short and commodious proves to be divided, either by the separation of two rocks or by hollows. As these breaches, however deep they may be, cannot be all of a certain breadth, therefore, in order to avoid marching over the unnecessary ground that going round them would take up, bridges should be thrown over, if possible, from one rock to another.

But as in a march, whether in an open or in a mountainous country, occasions for throwing bridges very often present themselves, it is very necessary to say a word or two relative to the manner of their construction.

Six or eight thick pieces of timber are laid across a rivulet, or any other bad place necessary to be passed, at six feet distance from each other; these must be crossed again by other pieces of timber not so thick, at the distance of three feet from each other; which must be fixed to one another by large pegs, and faggots well fastened together must be laid over them. When the bridge shall be thus covered, some earth must be thrown over it, which ought to be well trampled, in order to fill up the vacancies of the faggots; and then, for the greater firmness, new earth should be thrown over it, which ought to be well beaten down. The bridge thus made, the troops, the artillery, and the baggage, will pass over it with great ease.

It must be observed, that the bridges should be of the same breadth with the roads; they should be broader rather than narrower, because, exclusive of the danger the artillery and baggage would run if they were narrower, the ranks being obliged to be straitened and the column to be lengthened, the march would of course be retarded, and it would be difficult to avoid confusion. The labourers that accompany the detachment ought to be furnished with every sort of tool necessary for the removing of earth, the felling of trees, and working and fitting them for use.

This detachment being divided, as has been already observed, into as many bodies as there are roads through which the army is to pass, will meet again at the place from whence it is parted; and the reports of the commanding officers of the different bodies being given to the lieutenant-general, he must make a report of the whole to the commander in chief.

On this report, the general will order as many detachments as there are columns intended to set out, two or three hours before the time appointed for the march of the army. These detachments will march carefully over the ways already examined and prepared: they will scower every thing, hedges, narrow passes, entrances of passes, woods, heights, villages, in short all that may serve as shelter for troops in ambuscade; and for greater security, they will post guards in the villages, which guards are not to retire till the rear-guard of the army comes up.

The commanding officer of each detachment should possess himself of the heights on the right and left, and should distribute platoons of infantry at proper distances from the rocks and narrow passes: he should be careful of what may be done to oppose him, and be attentive even to the smallest paths. When the commanding officer of the detachment shall be advanced

ced to the end of the passes, or to the ground intended for the camp, he will establish his infantry in the most advantageous posts; he will place his light horse or dragoons in the front, but within reach of assistance; he will send out patrols of light horse advanced before the infantry. If he receives any intelligence of the enemy, he will send immediate notice of it to the general; but if, from the report made to him, the enemy does not appear to be sufficiently strong to annoy the army on its march, or only some parties were willing to try if they could enter the passes, his detachment will be sufficient to keep them at a distance, particularly as he is in possession of the heights and the passes.

These troops, in the situation they have been placed, should wait the arrival of the campement. As soon as they perceive it, they shall advance; and whilst the major-general, assisted by the staff-officers, marks out the camp, they shall possess themselves of the villages, passes, and roads by which it is probable the enemy might come and make an attack. These detachments shall remain in their posts till relieved by the proper officers, which will not be done till the guards of cavalry and posts of infantry necessary for the security of the camp are posted. Then, although the army should be yet at a distance, it may on its arrival enter the camp, which will be found covered by the guards which escorted the campement.

With these precautions, if the enemy is at too great a distance to attack the army, the march will be performed without any trouble: there will be no obstacle in the roads, or reason to fear that the waggons will be mired; and if the wheels or axle-trees of any of them should break, they will be repaired from those which have spare ones: if, on the contrary, the enemy should be so near as to give cause to apprehend an attack, the necessary precautions are taken for forming the troops in order of battle, and for the necessary dispositions during the action.

It has been already observed, that an army on a march should be divided into as many columns as the detachments have found openings or roads leading to the camp the general intends to occupy; suppose two, the army will consequently march in two columns. The disposition of the troops in their march differs entirely from what it would be in an open country; the advanced-guard of each column must consist of infantry, some must be distributed either in the narrow passes or on the heights, and there should be some advanced detachments of light horse to scour the narrow passes: the rear-guard should consist of infantry only; the remainder of the troops may be disposed after the following manner:

Four or five brigades of infantry, according to the number which composes the army, should be placed at the head of each column; the same partition should be made with regard to the artillery, which must follow the infantry; the cavalry must march next, and the baggage of each column, well escorted by infantry, must follow the cavalry; then the remainder of the corps of light horse which are not detached; and the dragoons are placed the last, in order to dismount and sustain the rear-guard in case it shall be attacked.

Each column should consist of the same number of troops as well infantry as cavalry. Platoons of infantry should be detached to march on the heights, at

proper distances, in order to cover the flanks on the right and left. Care must be taken to march very leisurely in the front, otherwise the rear will not be able to keep up; then, in order to give the rear time to come up, the front will be forced to halt, by which the march will be retarded and the troops fatigued. See Plate CCLXXXIX.

These dispositions are necessary, because as the enemy in a mountainous country will be able to attack with infantry only, it is necessary to oppose him with troops of the same nature: the reason why the artillery is posted behind the infantry is, that in case the enemy should attack briskly in front, and the road through which the columns pass is broad enough, some pieces of cannon may be sent into the front, which firing with grape-shot will soon thin the enemy's ranks, and abate something of his ardour: if the road is too narrow, and there is not room for more than four or five men to march abreast, consequently the artillery must be carried on sledges, which has been often obliged to be practised in the Alps. In this situation resolution must supply the want of that assistance which the cannon would give, and the enemy must be charged with bayonets; which is the easier to be performed, as the enemy will not be able to present a larger front than that opposed to him by the army, which is also supposed to be in possession of the heights. The cavalry does not follow immediately, because, not being able to act in this sort of country, it must be covered by infantry. The baggage which follows is sufficiently defended by the columns that cover it, and the infantry that escorts it: this infantry should nevertheless join as often as circumstances will permit, without being fearful of exposing itself, that upon the heights being to reinforce it in case the head of the army should be attacked. The remainder of the corps of light horse being as incapable of acting as the cavalry, is free from insult: the dragoons which have been posted behind can, by dismounting, assist it if it is attacked. Troops thus distributed will march on securely; by this means those troops who can act with facility cover and protect those who cannot, neither will they be in the least embarrassed.

There are some mountainous countries so difficult of access, that it is impossible for the cavalry to follow, because some post must either be immediately seized, or the enemy, being in possession of the hills, must be driven from them before it can advance; or because it would be difficult for it to be subsisted.

If the army can march in four columns, the dispositions should still be the same; but as the head of the columns will be weaker in infantry, the heights should be guarded accordingly, and the rear-guard sufficiently strong to resist the enemy: the same disposition should be made for one column only.

If the march is to be made through a woody country, the precautions which have been already mentioned in regard to examining the ways through which the army is to pass, and for the detachments which set out in order to be before the army, should still remain; but the disposition and order of the troops are different. If by the situation of the country the army is obliged to march continually through woods till it arrives at the camp, the cavalry and the baggage should be in three columns in the centre; but some infantry should

The March of an Army through a Mountainous Country.

should be placed at their head and their rear-guard: the infantry should march in two columns, one on the right, the other on the left of the cavalry and baggage; some brigades of artillery should be distributed to each column of infantry, the remainder must march at the head of the columns of baggage; the flanks of the columns must be covered by platoons of infantry, placed about at proper distances, which are to follow the columns at 40 or 50 paces distance, without ever losing sight of them. See Plate CCXC.

If by the knowledge which the general has of the country, or rather from the report of the officers who commanded the detachment sent out to view, open, and repair the roads, he knows that the country is interrupted by woods and little plains, the disposition ought to be wholly changed; it will then be sufficient that the second detachment, which in other cases ought to set out the evening before, sets out only two hours before the campement. This detachment should be composed of infantry, light horse, and dragoons; the infantry to scour the villages and the woods, the light horse to penetrate into the woods wherever they can enter, and clear the march of the infantry, and the dragoons to sustain the whole.

When the disposition for the march of the army is supposed to be in five columns, the infantry should form two, the cavalry two more, and the artillery and baggage the fifth. If it is thought there will be any occasion for artillery, a brigade or two may be distributed to the columns of infantry; and the remainder may march at the head of the effort of the baggage, which is to be defended by the regiment of artillery; to which must be added a detachment of infantry, which will form the advanced guard. The cavalry and dragoons are to keep the open country as much as possible, and the infantry the inclosed; the dragoons and cavalry should avoid the woods as much as possible, and the best and most accessible road should always be given to the artillery and baggage. In order that the columns may preserve the same length in marching, a brigade of infantry should be placed at the heads of the columns of cavalry; if this precaution, which fixes the head of the columns of cavalry, is neglected, the cavalry will extend a great way before the columns of infantry, which should always be avoided. The rear-guard should consist of infantry, cavalry, or dragoons; the light horse should always march on the flanks on the right and left, and before the army.

It is after this manner that the march of an army may be disposed through a woody and a mountainous country; but an army must always suit its motions to circumstances, and to the situation of the country where the war is carried on. Were the general always free to choose his own route, he should sooner be determined by the nature and number of the troops he has with him, than by the goodness of the road: it is not without great difficulty that cavalry can act in a woody country; in a mountainous one they are of no use; there infantry only can be serviceable. If the general is inferior in point of number, he should always make choice of defiles; because in them he can always present a front equal to the enemy's. Who can be ignorant that Leonidas with 8000 Greeks, at the straits of Thermopylae, stopped the almost innumerable army of Xerxes, who was unable to force him?

A mountainous and woody country, when thoroughly known, becomes a more favourable theatre for practising the wiles and stratagems of war than an open country; it is true that the knowledge of it is more difficult to attain, and that it requires more vigilance and readiness in the general. Hannibal was even drawn into ambuscades by his own guides; an example worthy the notice of a general who takes guides that have either but little regard for him, or are unacquainted with the country: it is impossible to try them too much, and their ignorance is often more fatal than treachery itself.

The general should choose brave and active soldiers for the forming of the detachments which precede the army. It has often happened that guides, and even entire detachments, seized with a panic, have imagined the enemy where he was not; and by that means have missed the opportunity of finding him where he really was.

The places where the enemy can lay ambuscades ought to be known: neither is it always in the most hidden and secret places that they are to be found; they are often in those that are most uncovered; for the more open a place is, the less suspicion will there be of any ambuscade in it.

The marches that require most precaution are those made in the night, those made in sight of the enemy, and those that should be kept secret.

The first should be avoided as much as possible, especially in a mountainous country, because surprises are more unavoidable, and the soldier's fear, which always magnifies the danger he cannot see, renders those marches more difficult, and very dangerous. If the army is beat, the retreat becomes more fatal than the action itself: should it get the better, that advantage becomes useless, because it will not be able to pursue the enemy; whether on account of the ambuscades he may have laid to secure his retreat, or whether from the fear of losing the way. The Numidians, who had more cunning than strength in war, attacked Marius in the night; because, said they, if we are beaten, the darkness will befriended us in our flight; and if we beat the Romans, it will not prevent our pursuing a vanquished enemy through a country of which they have no knowledge, and with which we are perfectly acquainted.

But if circumstances require and force an enemy to march over a mountainous country in the night, care should at least have been taken that the roads have been well surveyed during the day; that the guides march at the head of the army; that the ranks are kept very close together, that the men may not lose sight of each other: and that part of the troops do not mistake one defile for another, which may easily happen in the dark, if the advanced guard has marched a little too fast, and the officers hastened too much. The Greeks, according to Xenophon, on like occasions, gave the heaviest arms to the troops that marched at the head, thereby to oblige them to proceed leisurely.

In those marches that are made in sight of the enemy, beside the precautions necessary to be taken for the safety of the troops, and which have already been mentioned, the general should endeavour to deceive them by false appearances, and by an ostentation, often, in such circumstances, necessary: as extensive a front as possible should be given to the army; the intervals

of the ranks and columns should be widened, but not so as to weaken them; the general should take advantage of an height, possess himself of it, and post some troops in it, in order to make the enemy suspect there may be still more behind: advantage should be taken of a wood, and, by marches and countermarches, the same troops should be made to pass and repass, in order to make the enemy believe the army stronger than it really is. There have been instances of generals, who, on like occasions, have made such good use of their ground, that, by the arrangement of troops, they have seemed to multiply them in the enemy's eyes; and who, although inferior in strength, appearing to have the advantage of numbers, have kept the enemy in awe.

But still, unless it is to deceive the enemy, a general should conceal his force and management: his force, because, if superior, he will not fail to profit by that advantage; and if inferior, he should avoid a battle: he will conceal his management, because he will prevent the designs of the enemy's general, who will receive as much information from his successes as from his mis-carriages. Pyrrhus, who taught the art of war to the Romans, was in the end conquered by them. The Mexicans often turned the arts and wiles of Cortez and the Spaniards against them; and the czar Peter I. never regretted a defeat when it became the means of instructing him how to conquer in his turn.

It is impossible to lay down fixed rules for secret marches: it is by his address that a general will improve circumstances; it is by art and contrivance that he will evade the enemy's vigilance, and deceive his spies. The march performed by the great Condé and M. de Turenne, in 1674, may be seen, as related by M. de Feuquieres in his memoirs.

However difficult it may be to attain a thorough knowledge of a mountainous country, this march certainly supposes, in the two princes who executed it, the most digested study and the deepest knowledge: the justness of the orders, and the exactness with which each commander arrived, almost at the same time, on the spot where they were to assemble in order to make the attack; and the infinite precautions they must have taken for the subsistence of an army, that, during a march of eleven days in a barren sandy country, wanted for nothing, are circumstances not to be sufficiently admired.

If, in the passing of mountains, there is only one passage, it is often by art than by force a general can get possession of it. The duke of Valentino intending to pass through Tuscany, and fearing the passage of the Alps would be shut against him, sent to demand a passage of the Florentines; but during that negotiation he passed the Alps, without waiting for their answer.

If there are many issues, they must all be guarded, and not one of them neglected. In 1515, Francis I. desirous to pass into Lombardy, and being also apprised that the Swiss waited for him at the different openings of the mountain, sent detachments towards each of these places, as if he intended to force them; and whilst he, by this means, kept them in suspense, he passed with his army through another opening which was shown to him by a peasant. But if it is impossible to deceive the enemy, and if circumstances render stratagems ineffectual for concealing of the march, all possible care must be taken: any, even the most trifling

thing, may cause a discovery; the neighing of horses, the light in a pipe, the noise of the arms, &c. during the night; and in the day, the dust, and the sun-shine glittering upon the arms. During the march, all these inconveniences must be guarded against as much as possible, by recommending silence to the men, while in woods and passes; by leaving the horses and mares behind, if they neigh to each other, and also every thing that can contribute to noise.

But if, notwithstanding all these precautions, an enemy superior in force is in possession of a pass from which he cannot be dislodged but by art, a feint should be made of attacking some post, in order to draw the enemy; from the pass and possession should be taken of whatever the enemy abandons, or withdraws his troops from. The general should make diversions, pretend retreating, and even flight: he should observe whether there are any heights commanding those occupied by the enemy; add if there are, he should attack the enemy on the side next them; so that whilst the enemy is taken up in defending himself, the troops may seize on that post which overlooks him: art and force should be employed by turns, and should be blended together as often as possible. A Greek general set fire to a wood which was at the foot of a mountain in the enemy's possession, and which he wanted to go over; the flames and smoke forced the enemy to abandon it, and leave the passage free to him.

General rules only can be given of the dispositions to be made of troops upon a march; particular ones would be merely conjectural, because the general of an army must always depend upon circumstances: it is the situation and nature of the country, the number of troops, the nearness of the enemy, the facility of foraging, and the passes of which the enemy is possessed, that ought to determine him.

In a word, whatever is the order and disposition of the troops, it must be such, that they shall always be able to sustain each other; that the flanks shall be well guarded, and the fronts secured; the roads must have been surveyed and opened; and whatever the nature of the country is, all the columns should arrive at, and enter the camp at the same time.

SECT. VI. *Of Camps in defensive War.*

It is in general more difficult to carry on a defensive war, but more particularly so in an open than in a mountainous country. In the former there is nothing to conceal the movements and dispositions of the army from the enemy, whereas in the latter the nature of the places prevents the enemy from discovering them: but whatever may be the nature of the country, the choice of a camp when on the defensive, and the art of pitching upon an advantageous situation, is what proves the genius and talents of a great officer. Exclusive of a thorough knowledge of the country, this operation requires a quick and penetrating eye in a general to enable him to seize the posts which from their situation may prevent the enemy either from attacking him or penetrating into the country. It is not difficult for a general to stop an enemy by his courage, when of equal force; it is still easier to prescribe bounds to him when he hath the advantage over him in number: but a general, under the necessity of receiving them, must seek for such expedients from his

own

Plan of the March of an Army through a Woody Country.

own talents and understanding as may serve to balance the enemy's superiority, or make himself equal to him in strength.

A general who acts on the offensive takes what state or circumstances he pleases; he may act as he chooses, and is not under a necessity of regulating himself entirely by the enemy's motions: whereas a general that is not sufficiently strong to attack, is commonly obliged to continue quiet till the enemy hath acted, and then to regulate his motions according to those made by the opposite army, unless his superior abilities give him a particular advantage over the enemy's general.

Although it is always necessary for a general to have a thorough knowledge of the country, this knowledge will yet become more necessary to him when acting on the defensive. He ought to prevent the enemy's entering his country and forming any siege there (a plan which he cannot execute, unless he is possessed of the most advantageous posts, and also of those which cover the towns liable to be threatened) by proper dispositions that secure his camp; by covering his fronts and rears, and keeping the communication between the camp and the places where the magazines are; by endeavouring to annoy the enemy in his convoys and foragings; by harassing him in his camp, and perplexing him with small detachments, to which the enemy will be obliged to oppose more considerable ones: these dispositions, properly managed, may destroy any enterprises the enemy may have formed against the army.

By the enemy's superiority, the nature of the country, and the success of campaigns, the general should determine whether or not his camp should be entrenched: the entrenching of camps requires much observation. It is easy, says Vegetius, to entrench a camp while at a distance from the enemy; but it becomes a very difficult operation when the enemy is near at hand. The Romans, according to him, used to keep all their cavalry and half their infantry drawn up in order of battle, in order to cover those troops that were employed in working at the intrenchments. Cæsar, when in Sapin, fortified himself after this manner under the eyes of Afranius and Petreus, without their having the least knowledge of it.

Before a general fortifies a camp in a plain, he must observe the position in which the ground will permit him to form his camp; whether or no it will be liable to be surrounded; if it will entirely cover the country it is to protect, and the towns for which there is most reason to be apprehensive; if the parts in the rear are open; if forage is in plenty; if provision can easily be brought; if there is wood and water; if it is impossible for the enemy to enter the country without forcing the camp; if all these circumstances concur, it is certainly most advantageous to entrench the camp.

A general should never be too secure by having a superiority of numbers; he ought not on that account to neglect fortifying his camp: even when he acts on the offensive, these entrenchments will not hinder him from marching out to the enemy whenever he judges it proper, and his army will by that means be sheltered from the enemy's attempts.

Cæsar, whose good luck was equal to his intrepidity, after having ranged over all the territory of Beauvais,

like a conqueror certain of victory, being distressed for forage, was consequently obliged to weaken his army, in order to increase the detachments which he sent out to forage; he therefore first took the precaution of surrounding his camp with all necessary fortifications.

If a general is fearful of fatiguing his troops or weakening his army by employing part of it at these works, he must, for that purpose, make use of all those who follow the army: they will work equally the same as the soldiers; for nothing will render men so industrious and laborious as the common danger to which they are all exposed: As formerly, at the siege of Carthage, the women, the children, and the old men, all worked; and their united labours retarded, at least for some time, the taking of that city: Cæsar, that he might not fatigue his troops, employed only peasants to entrench his camps.

There are many methods of intrenching a camp by lines beginning on the right, and covering the whole front of the camp to the left; these lines, in their extent, have redoubts and angles at proper distances; and the line being continued from one to the other, forms the curtains. In the front of them there is a large and also deep ditch; sometimes a covered way is added, which is a palliased and floccaded throughout the whole front of the lines. To render them yet stronger and more difficult to be forced, there are pits sunk before the covered way. These pits are ranged chequer-wise, about six feet deep and five broad, and are in form like a reversed cone. Such were the lines which the duke of Berwick caused to be made in 1734, to the lines of circumvallation before Philippsburg; only with this difference, there was no covered way. Without doubt these lines are formidable, and even very difficult to attack; but a great deal of time is required for constructing them: and if there is not a sufficient number of peasants in the army to work at them, troops must be employed to expedite them; which will not only greatly fatigue them, but may also cost the lives of many; because removing of earth often causes great disorders, particularly where the ground is swampy or clayey. Besides the time which these lines take in raising, they are generally defective; and there are but few instances of their being attacked without being forced; and if the enemy penetrates at any one part, the troops which guard them are obliged to retire to avoid being attacked in front and flank.

The method practised by marshal Saxe seems much superior to these lines. It contained as large an extent of ground, without diminishing the labour; because, instead of lines, it consisted of redoubts, which require as much work to form the four faces and the covered way, as lines always continued. At the siege of Maestricht in 1748, he used these redoubts instead of lines; their distance from each other was 48 yards; they were floccaded, and the covered way palliased. These redoubts present an angle to the field, and consequently were a mutual protection to each other; they were each of them capable of containing a battalion.

His design was, supposing the enemy was come to attack the army, to cause all redoubts to be occupied; to plant ten pieces of cannon between each, and to draw the army up in order of battle behind them: by this means the enemy would be obliged to force the

Defensive Operations

redoubts before they could attack the army, which could not be done without great loss. But supposing the redoubts to be forced, how would the enemy be able to enter the intervals without dividing? The army behind, in order of battle, would charge him, without giving him time to recover himself, and it is highly probable would beat him.

By following this method of entrenching a camp, if some of the enemy's battalions should, for example, force three of four redoubts, they certainly will not dare to advance as long as the remainder hold out; so that a general might, by detaching some brigades, and causing them to march to the assistance of the battalions that have been forced, retake the redoubts; or, without disordering the order of battle, may drive away the troops which are in possession of them with his cannon. In short, this method seems to be excellent, because it proves, that all the redoubts may be forced, and yet the army not be beaten, because it has not suffered in the action, but remained the whole time in order of battle with all its cannon; so that the enemy will be reduced to the necessity of beginning a second battle. Lines, on the contrary, have not the same advantage; all the troops, or the greatest part of them, must line them; the cannon is planted at proper distances either on the angles of the redans, or those of the redoubts. If one part only is forced, the army is beat, and the cannon taken, because the enemy makes the attack with his whole front; and the front of the army being broken and taken up, the troops which have entered, seize on the flanks of the lines, and consequently the army is surrounded, unless it immediately retires.

Lines are never good, unless when there is a large extent of country to be guarded, and some frontier to be covered from the incursions of the enemy: the front of an entrenched camp seldom exceeds six miles, more or less, whereas lines to cover a country have sometimes extended thirty miles in front. By some it is thought, that, in order to cover a country, it is sufficient to have certain holds, which shall be strong and well entrenched, with patrols continually going from one end of the posts to the other, and each post to be provided with signals both for day and night. It is unnecessary that these patrols should be strong, provided they follow and are continually crossing each other; this will be sufficient to prevent the enemy passing undiscovered. It is certain that the enemy will not dare to pass between these posts, whether he be strong or weak: if he pass in a body, he will be cut off behind, and his convoys intercepted; if he pass only in parties, they will be cut off with the greater ease. However, lines of this nature would require much labour, and also take up years to complete them.

The lines of Stolhofen are a proof, that however well fortified lines may be, they are not impregnable. The prince of Baden had employed a considerable time in the construction of them, had neglected nothing, to render them formidable, and they were deemed impossible to be taken: nevertheless, M. Villars forced them in 1704, without the loss of a man. There are many instances of lines, which, encompassing a large extent of country, having been forced: those of Flanders guarded by the French were forced by the duke of Marlborough in 1705, and many others

which are needless to mention.

Marshal Saxe's method for entrenching a camp in a woody country interperfed with small plains, seems also to be a very good one. The redoubts are to be erected in the plain; and lines thrown up in the woods according to the usual method, with redans placed on the side of each other, at 24 toises distance: there should be a palliaded ditch in the front, and the lines as well as the half-moons should be fringed with pointed stakes: behind these lines, which cannot be very extensive because they only cover part of the front of the camp, must be placed the troops necessary for defending them; a considerable intrenchment of felled trees must be made behind with the branches of the trees entangled with each other, and some openings must be left wide enough to permit the troops who guard the lines to pass through, in case they should be overpowered and obliged to retire: the cannon must be planted in the face of these openings; and the remainder of the army must be drawn up in order of battle, 100 paces at most behind the intrenchments of trees and the half-moons.

The retrenchments of trees are placed about 60 or 80 paces behind the lines, and not before them; because it will be a new and unexpected obstacle to the enemy. These retrenchments, carefully made, and with large trees, can be destroyed by cannon only, which would take up a considerable time: if they were in the front of the lines there would certainly be a rampart more; but that might be useless and perhaps hurtful, because the fire of the enemy to make a passage, would drive the splinters of the trees into the lines, which would do more harm than even the shot itself. See Plate CCXCII.

In a mountainous country the dispositions for intrenchments are different: it is impossible there to find plains sufficiently large to draw up an army in order of battle, and place it beyond redoubts, as in an open country; the avenues and the passes only can be entrenched; the redoubts would not be sufficient, because the avenues not only must be guarded, but the heights also occupied. Now, as it will often happen among mountains that there is not a foot of earth, how then can redoubts be erected there? A general must then make use of such assistance as the country can furnish him with, whether by heaping stones upon each other, or by retrenchments of trees well joined; and thus construct lines sufficiently strong to shelter the soldier from fire and all injury. In an open country, a general in a manner suits the ground to his dispositions; in a mountainous country, he must apply his dispositions to the ground; but in any country whatever, he must use all the assistance of art for entrenching of camps. In mountainous countries there are more inequalities of ground, which render the enemy's approach to the lines difficult; and although it is almost impossible for a camp in a mountainous country to be attacked in front, nothing should be neglected for its safety: but all the avenues by which it may be surrounded must be entrenched with care, and all the heights which overlook it secured; because the enemy, without intending to attack in front, will amuse him during the time necessary for troops to take a long round, in order to penetrate to the camp on another side. If Leonidas, with his 8000 Greeks, had been possessed of all the avenues, ways, and heights, by which he could be cut off, in the same manner as he was of the passes

Plan of an Infringed Camp.

pafs of Thermopylæ, Xerxes with his innumerable army could never have forced him in the defiles which he guarded. The three actions of Fribourg are memorable examples of the necessity of securing all parts in the rear, and of occupying the posts by which they can be turned. M. de Mercy, attacked by two generals of the highest reputation, the great Condé and the viscount de Turenne, took such good positions in these three attacks, that, although forced to retire and followed from post to post, he could never be turned, but made his retreat quietly through the valley of St Peter, without the French army's ever being able to break in upon him.

The intrenchment should never be more than 250 or 300 toises, which make from 500 to 600 paces, distant from the camp, and which ought to be divided into three parts. This distance should be made, that the troops may be able to judge of the parts that can be carried with greatest ease, and of those which are most in need of assistance, that they may march there with greater order, dispatch, and facility: whereas if this distance is not observed, it will happen, as hath been sometimes seen, that the troops not having ground sufficient to range themselves in order of battle, the dispositions will be impeded by confusion and disorder, and the enemy will have forced the lines before the troops can be in a condition of opposing him.

But in a mountainous country, it is not sufficient for a general that he cannot be turned; that he hath profited so well by the advantages of ground, as to render the enemy's approach to the camp difficult; that the assistance of art hath been joined to nature, and that the country to be guarded is entirely covered: he must also be careful that the communication with the neighbouring towns where the magazines of war and provision are established, is safe and easy. If any one of these particulars is neglected, the camp is exposed, neither can the general continue in it the time that would be necessary to retard the march and designs of the enemy. As it hath been already observed, that there is scarcely any post that is not liable to be turned or overlooked, the camp should be entrenched only so far as the entrenchments may become an obstacle to the enemy, and as they may be a means of giving the general time to retire to occupy another post.

When the enemy undertakes the siege of some town, and the general, although with an inferior army, is willing to succour it, or cause the siege of it to be raised, he should seek out a spot naturally strong, and entrench it according to its situation: if an open country, according to the method above mentioned; if among mountains, according to the assistance that the nature of the country may give; and make use of these entrenchments as a sure asylum from whence to make sallies upon the enemy, to attack his forages and his convoys, and to oblige him to raise the siege as well by the fatigues of it, when it hath been drawn out to a greater length of time than was designed by the enemy, as by the want to which he is reduced by the continual inquietudes that the intrenched army hath given him.

When an army is in an open country, it generally continues in the same camp for some space of time; because it is certain the enemy cannot conceal his designs so effectually from the general, but he may be able

to circumvent them; but in a mountainous country it is uncertain whether an army will continue in the same post till morning that it occupied over-night. A general must then encamp in such a position, and after such a manner, that in case the enemy comes to attack him in force and with advantage, he may be able, without danger, to proceed to another post, and evade the enemy's designs.

It requires great skill in a general to judge when it is proper or improper to make choice of places which have a great many avenues on one side; because if he should be attacked in a camp inclosed by rocks, or deep in a valley which hath but one or two passes open, it will be very difficult for him to disengage himself from the enemy: on the contrary, if there are many small passes or avenues to the ground of which he is possessed, and by which the enemy may easily invade his camp, it will require a great number of men to guard them. But on these occasions a general should be ever careful to make a good disposition of his troops, to maintain strict order and discipline in his camp, and to find out his patrols with the greatest regularity; by which means he will free himself from all apprehensions of being surprised.

There ought to be no difference between a well-governed town and a well-ordered camp; the exactest order should be observed, and the strictest discipline kept up: if a soldier is at liberty to quit or enter it at pleasure, the enemy's spies will not fail to make their advantages of it. If the camp is unhealthy or distressed for provision, water, wood, or forage, and the soldier hath real cause of complaint, every method should be tried to avoid the danger that will attend his being discouraged. It is often owing to the little order existing in the camp, that the soldiers are seized with a panic, occasioned by the absurd and groundless reports that are diffused throughout it; troops thus terrified, are in a manner vanquished before they come to action.

In a mountainous country, such places should be avoided as are subject to be overflowed, either by the melting of the snow, or by torrents which, at some seasons, appear no more than trifling rivulets, but which, at others, swell and carry off every thing they meet with in their way: of this nature were those mentioned by M. de Feuquieres, which he found near the rock that he attacked and took in 1690 near the Badouais. Situations in the neighbourhood of woods are generally to be feared, because the enemy may set them on fire, and the flames be communicated to the camp. The general ought also to satisfy himself with regard to the nature of the springs, which may agree very well with the inhabitants, but prove very unwholesome to strangers: such, according to the reports of the French, is the nature of the springs in many parts of Italy. The water belonging to certain streams or rivers will be pernicious, while that belonging to the fountains and wells in the same country will be very wholesome and salutary.

The reader may see in Vegetius, Santa-Cruz, Montécuculli, and Puyégur, the kind of order necessary to be observed in a camp, whether entrenched or not: it is impossible to use too many precautions for its security; they depend upon the general's ability, and upon the discipline he causes to be observed.

SECT. VII. *Of escorting Convoys.*

THE conducting of convoys is one of the most important and most difficult of all military operations. In the escort assigned them, and the number of horse and foot of which this escort is composed, the general ought to be guided by the distance of the town from whence they set out; the dangers to which they are exposed from the different parties they may meet; the distance and strength of the enemy, and the extent and nature of the country they have to travel over, whether an open or a mountainous one; the number of waggon, and the quality of the convoys, whether they consist of money, or ammunition for war or provision; and whether they are extraordinary or daily. When escorts are too numerous, the troops are fatigued, and no end answered; and when they are too weak, they are liable to be beaten. M. de Puyfégur observes, that it is as dangerous to give an escort of 2000 men to a convoy where only 1000 are requisite, as to give but 500 to one where 1000 are absolutely necessary; in the first the troops are unnecessarily fatigued, and in the second the convoy is exposed to the danger of being carried off.

All these considerations suppose the general to be a man whose natural parts are matured by experience, and who is sensible that, without a thorough knowledge of the country, the foundation of all conduct, it will be impossible to make a proper disposition of troops. If a general is ignorant of the places most proper to form ambuscades; of those where there are bridges and fords; of the passes which are most dangerous, and those which will favour the enemy's approach in order to attack, and whether in head, flank, or rear, he acts but as chance directs, and his dispositions will have no meaning, either with respect to the situation of places, or the nature of the ground; the orders will be ill executed, the evolutions performed without exactness, and the disposition of the troops will be faulty; the separate bodies being, consequently, unable to sustain and assist each other, will soon be beaten and dispersed, and the convoy carried off.

The general officer commanding the convoy ought, for its security, to distribute his troops after such a manner that they may be a mutual assistance to it. The choice of the troops to form the escort is undetermined, as it is by the nature of the country their quality should be decided. In mountainous and woody countries, only infantry, hussars, or dragoons, can be made use of; the hussars or dragoons are to march in the front and on the flanks, to scour the woods, examine the avenues, and make sure of the defiles: in an open country, the escort should be composed of infantry, cavalry, hussars, or dragoons. But whatever may be the nature of the country, the convoy ought never to advance without first sending out detachments to reconnoitre at a distance.

If the convoy marches through a mountainous country, a large body of cavalry would not only be useless, but also an embarrassment, as it would be unable to act, except with great difficulty; whereas, in an open country, cavalry is very serviceable. In any kind of country a convoy can be escorted with infantry, especially when the enemy can only act with his; but as in an open country it is necessary for the infantry to

be supported, the cavalry must be used for that purpose. In a mountainous country, infantry can carry on war alone.

In this last case the officer commanding the escort ought to place a body of infantry at the head, another in the centre, and a third at the rear-guard; to distribute small bodies at proper distances on the right and left, and he should be particularly careful to possess himself of the heights. The hussars must be distributed to the advanced and rear guards, and, in order to be more certain that every part hath been strictly examined, as the convoy advances, notwithstanding the hussars of the advanced guard have already scoured the avenues, woods, valleys, villages, and hollows, the hussars belonging to the rear-guard should again look into those places, to see whether any thing hath escaped the notice of the advanced guard. These precautions are never without their use, and do not in the least retard the march of the convoy.

The small detachments should advance as far as possible into the country, without exposing themselves to the danger of being cut off, the hussars with pistol or musketoon, and the dragoons with their carbine in hand, in order that if they should meet the enemy, they may, by firing, give the officer commanding the escort notice of it, so that he may have time to make his dispositions for defending and preserving the convoy. The convoy may continue marching on, till the enemy is discovered: but on the first notice of him, it must stop, and the officers belonging to the convoy should park their waggons; or, if the ground will not admit of that, they should cause them to keep very close together, and double them up with the distance of four paces, which should be filled with infantry, between each waggon. By this movement the length of ground taken up by the waggons will be contracted, the troops will be brought closer together, and will form a stronger and heavier body, capable of assisting each other with more ease.

In a mountainous country it is very seldom, and almost impossible, for the enemy to attack the advanced and rear guards and the centre at the same time. Nevertheless, if he should find an opportunity of forming these three attacks at once, by following the dispositions above mentioned, he will find troops at every part to receive him: neither will he be able to make himself master of the heights without attacking them, and the troops already in possession of the ground will easily repulse him; and by the assistance which the officer commanding the escort should endeavour to send them, they will be enabled to maintain themselves in them, to protect the convoy, and the enemy will be unable to attack by more than one or two passes.

If the enemy forms but one attack, only a part of the troops must be opposed to him, because it is to be supposed this attack may be made only with a design to draw the whole strength of the detachment to that part, and which, by being altogether in that one place, will give the enemy concealed in ambush an opportunity of falling with ease upon that part of the convoy that is unprovided with troops, and which will of course be incapable of making any defence. The troops of the centre should never march to the assistance of the advanced guard, if it is that which is attacked, nor those of the rear-guard to the assistance of the

centre;

centre; but a party from those troops which cover the flanks of the convoy should be collected in a body, and sent to assist the part that is attacked. However narrow and confined the country may be, a convoy may be easily conducted by infantry, when it would be impossible to do it with cavalry.

When any pass or avenue crosses the road on which the convoy marches, it should be covered by a body of infantry, which will remain there till the rear-guard is come up; then it will fall into the post assigned it for conducting the convoy. It is always to be supposed, that this pass hath been examined by the advanced detachments. If the escort is composed of infantry and dragoons, the latter should be dismounted, in order to give an additional strength to the guards, and their horses may be tied to the waggons. The hussars, if the nature of the country renders them unserviceable on horseback, may also be dismounted; by which means, instead of being an embarrassment to the infantry, they will become useful to it. The nature of hussars is such as will admit of their being employed on every occasion; and although the difference of their arms will not permit them to be as serviceable as dragoons, they may nevertheless amuse a party of troops belonging to the enemy in such a manner as to enable the infantry to beat them, or at least to oblige them to retire.

Hussars are more particularly necessary in the escorting of convoys, because they scamper about on all sides, and are very active and ready in scouring a country thoroughly; they leave no place till they have perfectly examined it, unless the thickness of the woods, or any other unavoidable obstacle, should prevent their penetrating as far as they would otherwise do; and even then they protect the infantry, who can with greater ease pass into those places where the hussars cannot. Whatever country the convoy passes through, there should always be hussars with it; otherwise the officer commanding the escort cannot be certain that the country is thoroughly surveyed, because for want of hussars he must employ cavalry on that service. Not that there can be any doubt of the cavalry's exposing itself to danger with as much cheerfulness and courage as the hussars; but as the horses belonging to the cavalry are naturally heavier than those of the hussars, and often encumbered with forage, they cannot venture to a proper distance without running the danger of being taken, because they cannot retire with that expedition which is requisite: On the other hand, the hussar being more active, and more accustomed to reconnoitre, knows how to go over a country with proper caution and care to himself: besides, the trooper who is used always to march in a body, and to be under command, will have a very imperfect idea of the method of scouring a country. Although the disposition of the troops should always be regulated by the nature of the country through which the convoy marches, and by the nature and number of the enemy by which it is liable to be attacked, yet the general should never neglect, whatever his situation may be, to secure the head, centre, and rear. Before the convoy begins its march, the disposition in case of an attack should be settled; by which means the commanding officers of different corps will know where to post themselves, and after what manner to act at the time the attack is made,

By the knowledge which the commanding officer ought to have of the country, he will form a judgment of those places where it is most probable he may be attacked, and of course make his dispositions accordingly. In any disposition that may happen, a general should always foresee in what manner the attack, defence, and retreat, will be conducted.

When a convoy marches through an open country, the advanced and rear guards should consist of cavalry sustained by infantry; the infantry in the centre should be continued on the right and left of the waggons, and the cavalry divided into troops should be distributed on the flanks, at 100 or 150 paces from the infantry; squadrons of horse, intermixed with platoons of infantry, should be placed at proper distances on the flanks of the remaining part of the convoy. By this position, if the convoy should be attacked in head, centre, or rear, these squadrons and platoons should have orders to march immediately to the assistance of the party that is attacked.

The advanced detachments of hussars, and those upon the flanks, by giving notice that the enemy is at hand and coming to attack, will furnish time for parking the waggons and uniting the troops; in which case the infantry must form in the park, and the cavalry post itself on the flank of that front which expects to be attacked, and the hussars place themselves upon the flanks of the cavalry.

The attack of a convoy is always sudden and rapid, and the success of it is generally decided in the first onsets; and as the enemy, whether he succeeds in his attempt or not, must retire with great expedition, for fear of any succour that may arrive, it is evident that it can be attacked only by cavalry, hussars, or dragoons; there have indeed been some instances where the cavalry have brought infantry behind them. If the convoy has had time to park itself, the effort of the infantry can only be turned against that which is entrenched behind the waggons. The enemy's cavalry and that belonging to the escort attacking each other, will fight upon equal terms: but with regard to the infantry, it will be different; that which is sheltered by the carriages having a great advantage over that which attacks it. On the contrary, if the enemy's infantry is sustained by hussars only, they will be briskly attacked by the cavalry and hussars belonging to the escort, who will take them in flank and rear. The enemy's hussars being hemmed in, his infantry, for want of being sustained, will be easily beaten: part of the cavalry and hussars belonging to the escort, should be left in pursuit of the enemy's hussars, and the remainder ought to take his infantry in flank. If the enemy is beaten, as it is probable he will, his retreat seems impracticable, or at best very difficult; because, being deprived of his cavalry, he will be forced to make head against the infantry that attacks him in front, and to repulse the cavalry that harasses him in flank.

If the convoy, in an open country, is obliged to march upon a causeway, these precautions will still become more necessary: the hussars which are advanced, ought to examine the country very exactly; for it may happen that the country not allowing the carriages to be taken off the causeway in order to be parked, they must consequently be obliged to remain upon it; in which case they can only be doubled up,

the extent of ground contrasted, and the troops drawn nearer to each other, in such a manner as to become stronger and more closely knit together. The dispositions will then, in a great measure, depend upon circumstances; but they should nevertheless be so managed, that each corps may mutually contribute to the preservation of the convoy; and that from the resistance with the enemy shall find in every part, there may be time sufficient to send succour where it shall be most needed.

If the enemy gives ground, the general should be cautious of pursuing him too far, lest, if he should receive a reinforcement, the troops in pursuit of him, finding themselves at too great a distance, will not only be beat, but also be deprived of every method of retreating.

There are some occasions on which the enemy must not be pursued at all; such as when the armies are very close to each other, or the convoy draws near to some of the enemy's posts; because then, by the nearness of the army, the enemy's infantry can come to the attack without being under the necessity of mounting behind the cavalry, as it happened in 1747; when the French convoys which set out for Antwerp for Bergen-op-Zoom, were continually attacked by the infantry that was posted from Breda quite to Voude: in which circumstances the same dispositions should be used for its defence; and in case the enemy should be forced to retire, the commanding officer ought to be contented with having saved the convoy, and not pursue him, for fear he should find advantage from the nearness of the quarters, and receive assistance that might prove fatal both to the convoy and its escort. A general to whose care a convoy is intrusted, should never seek any other advantage than the conducting it in safety, even though he should be sure of beating and taking a detachment belonging to the enemy; a real advantage is often given up by endeavouring to follow an uncertain victory. There is less shame in being beat, when an officer hath done his utmost, and acted with propriety, than there is glory acquired in conquering when he hath exceeded the limits of his duty. An officer is no longer praise-worthy, than whilst he acts up to the orders he hath received with exactness and discretion; whereas he who, depending too much on his own courage, rashly suffers himself to be drawn on by the appearance of success, is not only charged with, but ought to be answerable for, the consequences.

If the convoy hath a bridge or a defile to pass, it is not only sufficient that the country, as far as the bridge or the defile, should be known, but also necessary that the hussars should pass over it, and take a survey of the country a great way beyond it. The time in which the hussars are reconnoitring, should be employed in making the waggons double up by four, eight, or ten in front, if the ground allows of it, in order to unite the troops belonging to the escort. The troops in the centre must join the advanced guard, and cover the carriages; the rear-guard form in order of battle, and face toward the country they have marched over; and the squadrons and platoons of infantry which marched on the side of the convoy, place themselves on the flanks, in order to cover them. When the country in front shall have been thoroughly examined,

the advanced guard and the troops belonging to the centre, covered by hussars, shall pass over the bridge, and advance far enough on the other side to give room for the carriages either to double up or to be parked. The corps of cavalry and infantry which marched on the sides of the convoy must be placed on the flanks, to protect them. As soon as the convoy and the escort have passed, the waggons must proceed, and the troops fall into the same disposition they were in before the passage; that is, if there is no alteration in the nature of the ground to make another disposition necessary: in that case, the commanding officer must give such orders as he shall find necessary. For the greater security of the convoy, a detachment of hussars should be left near the bridge, or the opening of the defile, till the rear-guard hath marched to some distance, which detachment will afterwards join the escort.

There still remains another disposition to be made in an open country, whether the convoy marches on a causeway or in the high road, which is to divide the escort into many equal parts, with troops of every sort belonging to each; the first body should set out an hour before the convoy is to begin its march, the second half an hour after, with orders to the commanding officers to scour the adjacent country with great exactness, and to be careful not to be cut off by any detachments the enemy may have in the country; for which reason these two bodies should never be more than three quarters of a league distant from each other, by which means they will be within reach of assisting each other. The body which sets out last should never be more than half a league before the advanced guard of the escort.

As the convoy is supposed to march through an open country, the above-mentioned distances are allotted between the first and second bodies, and between the second body and the advanced guard of the convoy; but if the country should grow rough and unequal, these bodies should draw closer together, and always keep sight of each other, so as to be able to assist one another in case of an attack.

When these bodies are set out, the general must put the convoy in motion, and form the advanced guard of one of the divided detachments belonging to the escort; the infantry of which detachment will remain at the head of the waggons, the cavalry shall march by troops 300 paces in advance, and the rear-guard must be formed equal to the advanced; but besides this rear-guard, there should be a body of hussars and dragoons reserved, to march a quarter of a league or more, according to the nature of the country, in the rear of the convoy; the remainder of the infantry shall be distributed at proper distances on the sides of the convoy, and the remainder of the cavalry shall be placed on the flanks of the convoy, about 300 paces distance.

The commanding officer should take care to keep some hussars with him, to scour the country round about the cavalry that are on the flanks and the rear-guard; and thus by running over the country again that hath already been examined by the advanced detachments, the commanding officer will be certain there is no enemy at hand.

There have been often instances of a swarm of hussars falling upon the rear-guard from woods, which have been reconnoitred, and where no enemy hath been

been found, and where they themselves were not half an hour before.

When a convoy happens to be of such importance that its being taken may influence the operations during the remainder of the campaign, the general should not only assign a stronger or more numerous escort to it, but should also send off detachments, which, without having orders to attack the enemy, should keep between him and the road that the convoy keeps, in order to oppose and baffle any designs the enemy may have formed carry it off. The following examples will show both the security and necessity of this method.

During the campaign of 1746, marshal Saxe, being encamped on the Orne, was in expectation of a considerable convoy from Judoigne. As its safe arrival in the camp was of great consequence, he caused the marquis of d'Armentieres, then major-general, to set out with a large detachment, in the night preceding the day on which the convoy was to begin its march, with orders to march on the side of Ramillies. At the same time, he caused another detachment to set out from the camp of his serene highness the prince of Clermont, with orders to march on the side of the abbey of Rame: these two detachments, by amusing the enemy on one side, and by entirely concealing the march of the convoy on the other, enabled it to proceed in security, and it arrived in the camp without having been at all molested.

In the beginning of the campaign in 1748, the same general having a design to lay siege to Maelstricht, and consequently having occasion for all his troops, was willing to throw a supply of provisions into Bergen-op-Zoom, as he was going to a distance from that place, and could no longer be in a situation of assisting it. For that purpose he ordered a considerable convoy, which set out from Antwerp for that town under a good escort; but in order to prevent an attack, which circumstance had often happened during the winter, and that with loss, the allies at that time occupying a chain of quarters from Breda as far as Voude, he detached the count d'Estrees with a considerable body of cavalry to march on the side of Breda, with orders to push on detachments almost to Voude. This detachment had two objects in view; one of which was to keep the allies in suspense with regard to the siege that was to be formed, and the other to cause them to remain near Breda. This large body of cavalry kept the allies, who were in the neighbourhood of that town, in suspense; during which interval marshal Saxe marched to Maelstricht, the allies not daring to attack the convoy, because they would have put themselves between the escort and the troops under count d'Estrees. From these two examples may be concluded the necessity of covering convoys of importance by detachments, independent of the escort assigned them. In short, a general should do every thing that will contribute to the security of his dispositions; and precautions ought never to be thought superfluous when they are managed with prudence, and have for their end the success of a well-concerted plan.

SECT. VIII. *Of Detachments for forming a Chain of green Forage.*

Those operations whose object is the subsistence of

the troops require the exactest precautions; for famine, as Vegetius says, proves oftentimes more destructive to armies than battles, hunger being more fatal than the sword. A general can defend himself against an enemy, however superior; but when forage and provision are wanting, there can be no hope remaining.

It is very difficult to provide a large army with forage; and a general often exposes it to inevitable danger, if he is not thoroughly experienced in this operation, or if he is destitute of that knowledge which at once presents all the wants of an army, and the means of supplying them, to his view.

Foraging parties, like convoys, are attended with a greater or lesser degree of danger, according as the country is more or less accessible, and the forage at a distance or near at hand. The disposition for the chain in an open country is different from what it must be in a mountainous one. When forage is within reach of the camp, and the enemy at a distance, fewer troops and attendants are required; because, in case of an attack, there is assistance near at hand: but in proportion as the forage is farther from the camp and nearer to the enemy, the precautions should be increased, and more troops should be allotted to the chain, which should also sometimes be furnished with cannon.

A general should never forget that maxim which says, The enemy must always be opposed by troops of the same nature as those with which he makes the attack: if the forage, therefore, is in an open country, the chain, as it is certain the enemy will be more numerous in cavalry than infantry, should consist chiefly of cavalry, and only have infantry sufficient to occupy such posts as are necessary to be guarded: in a mountainous country the dispositions will be quite different because, as it is impossible for cavalry to move easily, the chain should be strongest in infantry. In short, the number and quality of the troops for the chain should be regulated in the same manner as in regard to the convoys; in proportion to the nearness or distance of the enemy; by the extent of ground to be foraged; and by the nature of the country: and as marshal Puysegur observes, before the ground to be foraged is examined, there should be a calculation made of the number of horses to be fed, and of the fertility of the ground that is to be foraged; for if it is a plentiful spot, a less extent will be sufficient; if it is not plentiful, a larger must be taken; but in either case the chain must be always proportionable.

Before a forage is undertaken, the ground on which it is to be performed should be always thoroughly known; in order for which the general should send out in the evening, or the day before, the officer who is to command it, with a detachment, to survey the situation of the country; the places where he must post his troops of cavalry and dragoons; the posts which the infantry must occupy; the ground necessary for the foragers; that where the corps of reserve must be posted; and what part in the front of the chain it will be necessary for the hussars to scover. After having examined all these particulars, the officer makes his report to the general, who, from the account given him, will order the troops necessary to secure the forage, and render the execution of it easy. The chain of forage should be in proportion to the number of troops

troops that are to forage, as well as to the quantity of fown fields and the thickness of the grain. Besides the horse, dragoons, and infantry, there should be hussars to scour the country in the front of the chain: the number of them is undetermined, as it will be sufficient for them to cover and protect the front, and give the commanding officer immediate notice of every thing that makes its appearance.

If the forage is to be made at a distance from the camp, the troops destined for the chain should set out at day-break, or the evening of the foregoing night, as was done by marshal de Coigny in the campaign of 1735. This general being desirous of foraging under the cannon of Mentz, the troops taken from the army to form the chain, one body under the command of the count de Belleisle, and the other under the command of the marshal de Dreux, set out after retreat-beating, and at break of day the chain found itself properly placed. When the distance is not so great, it is sufficient that the troops set out at day-break, and the general will have time enough to establish his chain, especially as the ground and the posts necessary to be occupied have been surveyed two days before. The commanding officer must take care to establish the chain before the foragers arrive, and also that the hussars have scoured the country; first, because the foragers should not, by waiting, fatigue the horses; and secondly, that no trooper or servant shall pass; which will undoubtedly be the case if there is any vacancy where troops are not placed.

The whole of the troops should be disposed after such a manner, as to be able to see one another; and the vedets also, that are placed between the troops to prevent the foragers from passing, should be within hearing. The infantry should be posted in hollows and villages and behind hedges, with horse or dragoons to sustain it and support the flanks; and the disposition of the chain will be still better, if these troops can be mixed with it, provided the infantry can be sheltered by any hollows, hedges, or bushes.

Grenadiers, sustained by horse and cannon, if there are any, should be posted on those sides which, either from the situation of the country or the nearness of the enemy, are most liable to be attacked; but in reinforcing these posts, the commanding officer must be careful not to weaken the chain too much in any particular part. When an enemy attacks a foraging party, he generally attempts to penetrate at different parts; but if he forms only one attack, the disposition of the chain becomes useless, as all the troops must be brought to that part where the attack is made. But as it is naturally to be supposed the enemy will form many attacks, particularly if his general acts like a man understanding his business, he must be strong in every part; the reserve, which is in the centre, will, with expedition and speed, send assistance to the parts which are attacked.

Before the commanding officer fixes the chain, he should detach some hussars to survey and scour the great exactness the woods, villages, hollows, and all such places, for at least three quarters of a league or a league in front, as may be capable of containing ambuscades: and during the time of this surveying, the troops destined for the chain will remain in

order of battle, in the front of the ground that is to be foraged, in order to cover it and protect the hussars, in case they should be attacked.

When this examination is finished, the commanding officer may begin to establish his chain, and the hussars will remain in the front till the foraging is finished; and will detach small bodies to march round about the chain, crossing each other, halting at times, and sending some hussars before them to patrol.

If the hussars gain intelligence of the enemy's being either in march, or placed in ambuscade, they will send immediate notice of it to the commanding officer of the chain, who should always fix himself in a particular spot, that there may be no time spent in seeking him; his post should be in the rear of that part of the chain that is nearest to and most in front of the enemy, and he will regulate the dispositions for his defence according to the report made to him. When an ambuscade is discovered, and troops marching to attack, a general should always suspect there may be more ambuscades, and more troops in march, to form different attacks; he must therefore, instead of weakening the chain in any part, strengthen it as much as he can, by causing either the whole reserve, or part of it, to march where circumstances shall require.

The avenues and the heights in a mountainous country should be occupied by infantry; the avenues, in order to prevent the enemy from penetrating into the valley or plain where the forage is made; the heights, in order to observe the enemy at a distance, and to prevent his getting possession of them, and flanking the troops which guard the avenues. In this case there should be a greater number of infantry than cavalry; no more of the latter being requisite than what is necessary to sustain and support the infantry, in case it should be attacked, repulsed, and obliged to retire through a valley or plain. Then, if it hath no cavalry to support it, the wings will be entirely exposed, and the enemy being superior, can at the same time attack the front and the flanks; whereas, by the means of horse, which can act with ease in a plain or a valley, this inconvenience will be prevented, and the infantry greatly assisted.

If the forage is made at a distance from the camp, and in the neighbourhood of the enemy, the infantry guarding the avenues should throw up some entrenchments in its front, which will be soon done; and it is then cannon becomes necessary, as there should be two or three pieces planted at each avenue. The heights also must, on every occasion, be occupied, which should be constantly observed as a general rule, whether the enemy is at a distance or near at hand, in every disposition that is to be executed in a mountainous country.

When the forage is made in an open country, the chain should be more numerous in cavalry than infantry; but some infantry is absolutely necessary to guard villages, hollows, and such other places as it would be difficult for cavalry to guard. In short, the number of the troops should always be in proportion to the extent of ground to be encompassed, and their species determined by the nature of the country that is to be foraged; and as it is generally known with what troops the enemy will attack, he must always be opposed by those troops from whom the best defence may be expected; and it would be still better to force him,

in some measure, to use troops of the same kind as those by which he is opposed.

If the enemy forms one or more attacks, the small efforts belonging to each regiment must join on the first order, and cover the foragers as much as possible, who should at the same time assemble in the centre by regiments. The foragers should always be provided with their carbine or sword; and although they may not be very formidable against troops completely armed, yet there have been instances where they have charged with success.

If it is in a plain, and the enemy, having formed but one attack, charges the chain in one particular part, the troops of horse and dragoons which are opposite to him should march up resolutely and sustain his efforts: if they are repulsed, they will be supported by the infantry that hath remained in its post; the hussars which were in front will unite, and place themselves upon the flanks of the troops which are attacked, in order to cover them, and endeavour to defeat the enemy by charging him in flank and rear. If the general is certain that the whole of the enemy's troops are engaged in this one attack, he may then bring up all the troops belonging to the chain, both cavalry and infantry, in order to oblige him to retire the sooner: which if he does, some hussars, sustained by horse and dragoons, should be sent in pursuit of him, till his retreat becomes certain; but with caution not to pursue too far, lest he should rally upon those troops, who, being too far from the chain, cannot receive assistance so soon as would be necessary; and besides, the making and accomplishing the forage being the grand object, the commanding officer should be contented with succeeding in that, without seeking for any other advantage unconnected with the original destination of the troops.

As soon as the enemy is retired, and the commanding officer is certain of his retreat, for he may return in greater force and with fresh troops, he will re-establish the chain, at the same time neglecting nothing that may contribute to its security. But if the enemy, instead of being forced to retire, should break into the chain, the commanding officer, who, on the first notice given him that the enemy was marching to attack him, had caused all the foragers to assemble in the centre, and to retire in good order, the small efforts forming their rear-guard, will then assemble his troops as readily as possible, and oppose them to the enemy, in order to cover the retreat of the foragers; always taking care to regulate his dispositions by the enemy's, and according to the nature of the ground.

If the enemy forms more attacks than one, the foragers, who, as hath been already observed, must be assembled in the centre, should have orders to take the road to the camp, and will re-enter it covered by the small efforts from the rear-guard: but as a forage should never be abandoned till the last extremity, they should be ordered to draw up in order of battle, when they are within a quarter of a league of the camp, in order to return and complete the forage on the first order. But if the enemy is in force, and by his superiority all hope of obtaining the forage is destroyed; or if it is made at so great a distance from the camp that the troops belonging to the chain cannot expect to be

readily assisted; the commanding officer ought to make a retreat, with every disposition a good officer is capable of, and to join courage and vigilance with knowledge and experience.

If, on the contrary, the enemy is weaker, or of equal force with the chain, he should be charged without hesitation; because the enemy, regulating his attack by his defence, will be obliged to contract himself, in order to make his attack heavier and more considerable; so that the troops being united, will charge the enemy: and if, by the assistance of the hussars who are advanced, and act after the manner already mentioned, the enemy is forced to retire, he must be pursued in the manner above directed; after which the troops must return and complete the forage.

As a commanding officer is, in case of a forced retreat after being beat, obliged to submit to circumstances, and regulate his dispositions by the enemy's; he must retire with the greatest order possible, causing the infantry to march in the centre, either in columns or in order of battle, as the situation of the ground will best allow, the horse and dragoons upon the wings, the hussars upon the flanks, that they may not confuse the dispositions, but serve as a support for the chain, and prevent its being taken in flank; and the disposition of the troops should be so managed, that the enemy shall not be able to present a larger front than that which is opposed to him: and although it is impossible for a general to foresee, for certain, what will be the dispositions for an attack and retreat, because they must be changed according as those of the enemy alter, or as the nature of the ground varies; they should nevertheless be so ordered, that each body shall be supported, and capable of acting without confusion. It is only on occasions thus pressing, that the commanding officer should suffer the forage to be abandoned; and even then it will be some satisfaction to the commanding officer that he hath been able to place the foragers and their horses in a state of security.

If, during the retreat of the chain, it should receive assistance from the army, it should charge the enemy, notwithstanding it may be too late to go on with the foraging; and if this charge should prove successful in either beating or causing the enemy to retire, he should be pursued without intermission, in order to deprive him of all desire for repeating the attack. In order to improve this advantage to the utmost, it seems probable, that the commanding officer should leave a large detachment, consisting of infantry, cavalry, dragoons, and hussars, to continue all night upon the spot, and the next morning betimes, the foragers, properly escorted, will come to take away the forage; and as soon as the effort is arrived in the front of the chain, the detachment which hath remained there all night, must return to the camp.

There still remains many other precautions to be taken for the security of foraging parties. If the nearness of the enemy renders the execution of them difficult, a greater number of troops should be employed to form the chain. Forages thus considerable should not be often repeated, because the army must necessarily be fatigued, by the number of troops absolutely requisite to form the chain; and the great distance will harass the horses, particularly on their return, as they will then be heavily loaded.

These.

These forages are not usual, except in cases where the general is willing to spare the forage in the neighbourhood of the camp, that he may, in the end, be provided nearer home. As a general cannot be certain how long he shall remain in the same camp, M. de Montecuculli, in this state of uncertainty, always advises foraging at a distance, and so by degrees to come nearer and nearer home; because, in proportion to the economy used with regard to forage, an army is enabled to remain longer in the same camp, and the troops less under a necessity of making fatiguing and fruitless movements: by foraging at a distance, the enemy is deprived of the means of subsisting, and is often obliged to quit an advantageous situation, in order to supply his necessities elsewhere.

Care must also be taken that the foragers, in entering the ground they are to encompass, do not occupy more than is absolutely requisite, and that they do not spoil more grain than they carry away with them; first, because by extending the chain it would be weakened, and become easier to be forced; and in the second place, every prudent officer should be an economist in the article of forage: the officers commanding the small efforts which march at the head of each regiment should be charged with the care of this. These officers will cause their troops to march as much as possible through roads and over grounds which are untilled, till they arrive at the place intended to be foraged. If all the grounds are sown, the commanding officer must cause the cavalry to dismount at the place where the chain halts, and part of the troopers furnished with scythes must go and cut the grain, while the remainder hold the horses, and when there shall be no farther room to fear damaging the forage, the cavalry will remount and take it up. Each place should be marked out for a brigade or a regiment, which distribution should be made by the staff-officers before the troops arrive.

The general officer commanding the chain should not assemble his troops till such time as all the foragers are gone off the ground; but nevertheless, in proportion as they retire, he may contract the chain, in order to give himself greater strength: the officers commanding the small efforts are not to depart without leave of the general, nor till the regiment they belong to hath completed its forage; then they will form the rear-guard, and on their arrival at the camp go and make a report of the forage to the brigadier and their colonel.

As soon as all the foragers are gone, the general commanding the chain will assemble all the troops of it, form a rear-guard, and cause the remainder to march with as large a front as possible; the rear-guard to the whole will be composed of some troops of hussars, and will keep at such a distance as not to embarrass the rear-guard in case it should be attacked briskly and repulsed; the remainder of the hussars will be placed on the flanks of the rear-guard, which must be composed of infantry, horse, or dragoons; those hussars which form the rear-guard of the whole should have orders to retire, in case they are attacked, to those upon the flanks of the rear-guard, and not to the infantry that forms it. By this disposition, if the general should be attacked in his retreat, the troops will be able to perform all the necessary evolutions, and to sustain each other, without the order of march being in the least destroyed.

SECT. IX. *Of the Detachments for forming a Chain of dry Forage.*

If there is great exactness and knowledge required in the conducting of parties for green forage, those for dry forage perhaps require more; and, in general, every thing that regards foraging parties, whether green or dry, excites a particular attention in the commander in chief; and, according to the chevalier Follard, all success in war depends upon secrecy, diligence, activity, and the thorough knowledge of the country.

The dispositions for forming a chain of dry forage, which differ from those for forming one of green, will direct the means for extending the chain in proportion to its strength, and at the same time place the foragers in security; although, in parties of dry forage, the foragers generally take up less ground, according to the distance of the villages, that are to be foraged, from each other.

The dispositions for a chain of dry forage are also varied according to the nature of the country; but whether it be open or mountainous, each different body should be placed in that part where it can act with the greatest facility; the infantry therefore should occupy the villages, and the cavalry the plain in front, and should be disposed after such a manner as to be able to retire easily to the protection of the infantry. Before the foraging is put in execution, the commander in chief should mark out the villages to the general officer who is to command the foraging party, and regulate their number by the quantity of troops that are to forage. The first dispositions will be the same with those mentioned in the foregoing section in relation to green forage: therefore the general who is to command the forage, ought to set out with a detachment in order to examine the ground, the posts necessary to be occupied, the villages which are to be foraged, their situation, the rivers which cover or run through them, the bridges to be guarded, the distance from one village to another, and with what degree of ease the communication with them may be secured. After having thoroughly examined into these particulars, he can with ease form a judgment of the number of troops that will be necessary to form the chain and secure the foragers: after having done this, he will order the bailiff or burgo-master of every village to come to him, and inquire of them the number of husbandmen, and how many ploughs each husbandman hath belonging to him; by which he will be able to calculate the number of sheafs reaped by each husbandman.

The general may, for every plough, reckon about 30 acres of ground; and, in proportion to the fertility of the ground, every acre will produce from 120 to 160 sheafs: by this method may be computed the number of sheafs reaped by an husbandman who hath three or four ploughs; and from this calculation the general will judge whether the number of sheafs, supposed to be in each village, will be sufficient for the troops coming to them.

Let every acre of ground be supposed to yield 144 sheafs; then a husbandman who hath three ploughs, will have reaped 12,960 sheafs; so by reckoning 12 sheafs to a truss, and every truss to weigh 600 pounds weight, this husbandman will supply sufficient for 124 trusses. It is true, that some deduction should be made from

from the number of trusses that every acre may yield, as the husbandman or farmer may have preferred or consumed some either for daily use or for feed.

It is very necessary that the general should take care to leave sufficient grain, not only to enable the husbandman to live, but also to sow his grounds; particularly if he foresees a probability of the next campaign being carried on in the same country.

Nevertheless, as this manner of reckoning may be attended with inconveniences, because there are some villages which keep up a particular trade of forage and grain, and therefore the granaries and barns may sometimes be found empty, yet the quantity of sheafs and grain remaining in the village may be calculated by the number of inhabitants to be subsisted. Marshal de Puyfégur's method, which consists in informing himself of the number of horned cattle and horses, and by deducting the time they graze, is a very good one; but still there must be some deficiency in this calculation, as it will be impossible to fix with certainty the time of their grazing.

When the general shall have arrived at a tolerable certainty of the quantity of forage; the ground where to establish his chain; the posts which the infantry are to occupy; and taken a note of the quantity of forage; he will carry away one or two of the bailiffs or burgo-masters, as hostages for the security of the forage: he will also direct them to inform the inhabitants, that if they conceal or purloin but even a single sheaf from the whole, he will cause their village to be first pillaged, and afterwards set on fire; so that the peasants, on whom these threats have often great effect, will scarcely give the enemy information of the intended forage. The general must leave some companies of infantry, sustained by a detachment of hussars, in every village, who, by constantly patrolling on the outskirts, will stop all comers and goers; while the infantry will keep a strict guard on the inside of the village, and permit no person to go out of it; nor suffer the bells to be rung, colours to be hoisted upon the steeple, or fires to be lighted; and will put a stop to every thing that may be supposed to be a signal agreed on with the enemy. When the general hath completed all these dispositions, he will return and give an account of them to the commander in chief.

The same general shall, upon the day appointed for the forage, set out at day-break, with the troops destined for the chain, and the staff-officers. As soon as he shall be got within sight of the villages, he will not fail to have them examined, notwithstanding he left troops in them the foregoing evening. When they are all examined, he will leave them in the rear, march on into the front, and draw up in order of battle; after that, he will form the chain, regulating the dispositions of it by the situation of the ground, and of the villages examined over-night. The hussars will advance three quarters of a league or a league, in order to scour the country; during which time the staff-officers, instructed by the general of the quantity of sheafs contained in each village, will, attended by the bailiffs or burgo-masters, make a distribution of the forage by regiment or brigade, and assign a barn to each, or one to two. When this distribution is made, the staff-officers will make a report of it to the general commanding the party.

In forming of the chain, the infantry must occupy the villages, hollows, and hedges, which may be found in the circumference of the chain, and the horse and dragoons will be left in the plain in the front of the villages, but within reach of being assisted and supported by the infantry; and care should be taken to have a reserve of such troops as can with the greatest ease transport themselves to those parts where assistance is needful: this reserve should be placed in the centre, or nearest to the part that is most exposed, or most liable to be attacked.

As all the villages marked out to be foraged are not in the same line, those which are in the rear, and covered by others in which there is infantry, and by the chain of horse and dragoons in the front, require but a small number of troops; and if a detachment of infantry is posted in them, it is more with a view of preventing the troopers and servants from marauding than any thing else.

The effort belonging to each regiment, commanded by a captain, should remain upon the spot where the regiment forages, and, with the assistance of the infantry, prevent disorder among the foragers, and send off those who are loaded. As soon as a regiment is set off, the captain commanding the small escort must report it to the general officer commanding the forage; after which he will follow, and form the rear-guard of it.

As soon as the general shall be apprised by the staff-officers, and the captains commanding the small escorts, that a village is evacuated, he may contract his chain, and draw it nearer together, till the foragers are gone; which when they are, he will assemble his troops, and detach as many platoons of infantry as there are villages: or rather the body of infantry posted in each village during the forage, should leave a party to make a strict search after all stragglers and marauders; the first they should keep with them, and make the others prisoners, and punish them severely on their return to the camp. When all the different bodies shall be re-assembled, and the officers commanding them have made the report, the general will order the hussars to be called in, and form a rear-guard according to the manner directed in the foregoing section, and return to the camp in the same order, and with the same dispositions, as if he expected to be attacked.

There still remains another disposition that will be executed with greater expedition, and prove more secure for a dry forage; that is, to observe exactly the same precautions which have been already mentioned, with regard to the detachment's setting out the evening or two beforehand, in order to get information of the quantity of forage, of the nature of the ground for the disposition of the chain, and the enemy's distance.

If the forage is to be performed at a distance from the camp, the general commanding it should set out in the evening at retreat-beating, with the troops destined for the chain, the staff-officers, and the majors or adjutants belonging to the regiments which are to forage: but if the forage is to be performed near to the camp, it will be sufficient for them to set out at break of day; and the commanding officer should always take care never to advance quite up to the villages, till they have been examined, notwithstanding

troops have been left in them the preceding evening; these precautions are always necessary, and can never prove useless. As to what remains to be done after, the same precautions which have been directed for the first manner of foraging must be observed.

These first dispositions being made, the general, from the knowledge he hath acquired the evening before of the quantity of forage contained in each village, will allot one to one or two brigades, or in proportion; he will next send the staff officers, with the majors or adjutants, to every village, and order them to make the peasants take all the forage out of the barns, and lay it in one or more heaps on the outside of the village; not in front, but in the rear of it, in order for the greater security, and every heap will be for a brigade. If the villages are so nigh each other, as to admit of the heaps of forage being placed together in the same field, the disposition will certainly become better; because the chain being more united, and taking up less ground, will undoubtedly become stronger, and that with fewer troops. But if the nature of the ground will not allow of this, the second method is in appearance the best; that is, to cause the forage to be placed in as many heaps, on the outside of the villages, as there are brigades; taking care, as in the first disposition, to have the hedges, hollows, avenues, &c. occupied by the infantry, while the horse and dragoons remain posted in the plain: the forage will be sooner completed, confusion avoided, and all marauding prevented; and if any information should be received of the enemy, the foragers can assemble with greater ease than if they were distributed in the villages. All the troopers and servants should have express orders not to enter the villages, under pain of being treated as marauders; and the general should be very strict in punishing all those who break through this order. Whichever method the general makes use of, whether that of leaving the forage in the barns, or that of placing it in heaps on the outside of the villages, it is necessary

the distribution should be made before the foragers arrive; and great care should be taken not to make them wait, which fatigues the horses more than the burthen they carry, although it is 600 or 700 pounds weight, the trooper included.

If this forage is made in a mountainous country, the disposition should be changed: the villages of mountainous countries are either in the avenues, at the entrance into the valley, or very much inclosed in them, or bordering upon the mountains. There are some mountains where villages are more frequent than in many plains; but in others they are scarce to be met with, and are more dispersed; therefore, in the first case, the extent of the forage will be less, but in the last it will be increased: but in either of these situations, a great deal of infantry is required, because, besides its taking possession of the villages which are to be foraged, it must also occupy the avenues leading to them, and the heights and roads in the front, which may be in these avenues. Among mountains, it is unnecessary to have any cavalry in the chain, unless there should be some plain where it can act and support the infantry, supposing it should be repulsed by the enemy's. None of the precautions above mentioned should be neglected; and if the general can pursue the method the proposed, and by means of waggons transport the forage of many villages into a valley or small plain, and then divide it into as many heaps as there are brigades, there should not at most be more than three hours taken up in the performance of it; and then it will be unnecessary to leave troops in the villages which are in the avenues, and already foraged; and it will be sufficient to place infantry in the entrances of the avenues, which may be in the plain, and on the heights by which it is overlooked.

When the foragers are gone, the general commanding the chain will assemble the troops, and march toward the camp in good order, as hath been already mentioned with regard to foraging in an open country.

PART II. OF the OPERATIONS of OFFENSIVE WAR.

JUSTICE and humanity having been considered, in this article, as the first principles of war, the chief intention of the first part hath therefore been, rather to convey maxims for a just defence, than to lay down rules for attacking. According to the original laws of nature, man, weak and fearful, was not desirous to attack; peace and self-preservation being in that state, according to M. de Montesquieu, the first natural law: but that timidity hath by degrees, and by the prevalence of the passions, been converted into fury; and man now imagines the security of his own being to depend upon the destruction of his fellow-creatures, his liberty upon their bondage, and his grandeur upon their depression. It is even possible that the authority which some have usurped over others, and the desire of appearing formidable, was originally owing to solicitude for their own safety; neither would it be impossible to prove, that the bravery and courage which have immortalised so many heroes, were, in reality, nothing more than the specious coverings of fear. This truth, seemingly paradoxical, is not less striking, if the cruelties, which have been at all times exercised against the

conquered, are properly considered. If conquerors fought only in defence of justice, and to punish vice, why should they be so strongly bent upon the destruction of their enemies? It is because, blinded by passion, they dread becoming themselves the victims of their revenge another time. Thus even attack may be proved to be only a necessary precaution for avoiding those dangers with which a man imagines himself threatened, and it may be also said to differ from defence only in superiority of force. This is one reason why the subject of attack has been reserved for the second part. By observing the various operations from the opening to the closing of a campaign, it may be seen, that the whole is nothing more than a series of defence, and that the fear of being attacked is the real source from whence these precautions for attacking spring.

SECT. I. Of Spies.

It is impossible for a general, or even for any officer charged with the command of a detachment, to act with certainty, if they have not spies or secret intelligence.

telligence dispersed about the enemy's army; they will have the mortification to see all their designs miscarry, and all their precautions will become useless, because they will be improperly taken.

Strade, Turenne, and Vauban, strongly recommend having them, whatever expence they may occasion: Vauban also adds, that a general had better be in want of many particulars, however necessary, than be destitute of spies. Nothing, says M. de Puysegur should be spared to procure them; and even the promises made to them should be observed with the most inviolable integrity.

M. de Feuquieres observes, that spies are of many sorts. They are to be found in the cabinets of princes, in the closets of ministers, amongst officers of the army, and in the councils of generals; in towns belonging to the enemy, and in monasteries: some offer of themselves; others are formed by the generals, or by the ministers; but the desire of gain is what chiefly encourages and tempts them to undertake this business.

Besides the spies of the cabinet, there are again others who make it their business to go from one camp to another, and give an account of all the enemy's transactions. Care should be taken that they are unacquainted with each other, and particularly that they are not known to any general or officer: they should be always spoken to alone, and never be suffered to meet each other.

The general should study their character, and prove them by repeated trials; he should sound them by degrees, beginning with things not difficult to be explained, and which, if discovered, will not be of great consequence; he should engage them in long conversations, thereby to form a judgment of their parts and comprehension; and he should also employ them often in bringing him intelligence.

Although a general should always be upon his guard with a spy whom he hath cause to suspect of treachery, he may nevertheless draw great advantage from him, provided he knows how to deceive him properly; because he may be very certain he will inform the enemy of all the resolutions which have been taken.

The emperor Leo, in his *Tactic*, advises a general, who hath reason to imagine his counsels are betrayed to the enemy, to conceal his real designs, by speaking in a manner quite opposite to them: For, says he in the maxims at the end of his book, an enemy must be deceived who receives intelligence from spies or deserters directly contrary to what is actually resolved upon; and should not the enemy give credit to their reports, he will of course neglect their intelligence, and then the general may take his precautions accordingly: but should the enemy repose confidence in them, he will be deceived, and consequently fall into the snare laid for him. But, adds he, should these spies be entrusted with the general's real intention, he should, by some alteration in his operations, endeavour to persuade the enemy they have deceived him; upon which he will grow mistrustful of them, and be obliged to look out for others, no longer daring to confide in the former.

If a spy employed by the enemy is discovered, and brought to the general, he ought to take him in private, question him with mildness, speak to him with a sort of confidence, and, instead of threatening, should

promise him a reward if he will discover to him what he knows of the enemy's intentions. If the general finds him intelligent, he should endeavour to engage him in his service; and, provided he can gain him over by force of money, a thing not difficult, he may derive great advantage from him; but he should be careful how he employs him, till he hath very good reason to be assured of his fidelity.

There are many different methods of trying the veracity of a spy: if, for example, the general receives information, that, on such a day, a detachment of the enemy is to set out on some expedition, he should then send out troops to double the number of those detached by the enemy; by which means, if the spy's intelligence is true, the enemy will not only be balked in his design, but may also be beat by the superior detachment. If the enemy's detachment has but a trifling object in view, it will be sufficient to send just troops sufficient to examine into the truth of the spy's report. The general may also pretend to appoint a foraging within two days, and order but few troops for the chain; in which interval, if the spy is false, he will find an opportunity of giving the enemy notice of it: but, instead of the few troops publicly ordered, the general will privately add another body to them, which will be placed in ambuscade behind the place where the pretended forage is to be made. If the enemy, in consequence of this information, should come and attack the chain, it should immediately retire, as if too inferior in number to continue the forage, toward the troops in ambuscade; when, being joined, they will fall upon the enemy on all sides, who will certainly be surprised at seeing the troops which he attacked so prodigiously increased, and attacking him in flank, front, and in rear. If this attack is made with vivacity and resolution, there may be great reason to expect it will terminate in a complete victory.

If, on the contrary, the spy does not appear intelligent, or affects stupidity, the general should punish him with death, and cause him to be hanged in the sight of the whole army, in order to deter others, which may be dispersed in the camp, by his fate. It would be needless to question him concerning the enemy, because it would appear inhuman to execute a man who had given intelligence of importance, whether extorted from him by fear, force, or perhaps a promise of pardon.

Spies are as necessary to a general, as arms are to an army: but it is money only that can secure their fidelity; and if a general finds himself ill served, it is because he has been too sparing of the funds intended by his sovereign for that purpose. Notwithstanding it is the duty of a good subject to manage his master's finances as much as it is in his power, yet there are intelligences of so great importance, that it is scarcely possible to pay sufficiently for them. A man is sufficiently indemnified when, by means of the intelligence he has received, he has concerted his measures in such a manner, as to beat the enemy, gain some marches over him, or to be beforehand with him in some enterprise.

The emperor Leo, in his *Sentences*, says, that spies should be resolute, industrious, and active. Spies thus qualified will be exact and true in their reports; but if they are trifling, vain, and timid, it is to be feared they will never be able to relate the truth.

Spies, when discovered, should not always be punished with death; great advantage may be made of them, by pretending ignorance of their real quality, especially if they are not sufficiently disguised. Tacitus, in his *Annals*, says, that Vitellius's party got information of Otho's designs by means of his spies, who, by endeavouring to dive too minutely into their enemy's secrets, did not sufficiently conceal their own.

Vigétius's method for discovering spies who are suspected to be ranging about in a camp, is to order all the soldiers and servants into their tents during the day, and the spies will be taken immediately.

The general should be careful that the spies are unknown to each other; for spies having a knowledge of each other may occasion great inconveniences, which may be very prejudicial to the schemes of a general or any particular officer. When spies are strangers to each other, a general is better served, and he can depend with greater security upon what they say; because, by being unknown to each other, he can try the fidelity of one, by comparing what he says with the reports of others: If they all agree in the same story, their intelligence should be looked on as certain; whereas, if they know each other, they can with ease cook up a tale among themselves, and not vary in their relation. Besides, a spy conscious of being known, always fearful of being sold, acts neither with confidence or resolution.

When a general is ignorant of the enemy's designs, he should always affect a knowledge of them; but whenever he is informed of them, he should, on the contrary, pretend to be ignorant of them; by which means the enemy, being easy with regard to his spies, will not alter his designs, or suspect the general of having any knowledge of them.

If the general can procure such spies as, by their employment, are near the person of the enemy's general; as, for example, a secretary, or any others who are near him, and who consequently can give intelligence more to be relied upon than those who are constantly passing from one army to another; and as it is very often by means of these people of consequence that common spies gain their intelligence, their service may be turned to a very great account.

If a general discovers an enemy's spy to be one of those who, by their employment, are near his person, he can receive great advantage, by forcing him to write a letter of false intelligence, thereby to divert the enemy's attention from the plan he would execute; but he should cause him to be hanged immediately after, for it would be very imprudent to use him above once. The prince of Orange, when he came to attack M. Luxemburg at Steinkirk, having discovered one of his musicians who gave the enemy intelligence of every thing he intended, made use of this stratagem; and although it was rendered abortive by the vigilance of M. de Luxemburg, and the courage of his troops, there are nevertheless but very few instances where it hath failed: and even M. de Luxemburg would have been beaten, if he had not had timely notice given him by his advanced detachments; by which means he had time sufficient to make his dispositions, and to avoid being surprised.

There is a stratagem which may be made use of when spies are wanting, and which is less expensive;

that is, to send supposititious letters by the first peasant that comes in the way, who will have nothing to fear; and to far from concealing himself, he must take a road where he will be sure of falling into the enemy's hands: these letters should be directed to the general officers commanding a body of troops, or even to the general of the army, supposing they come from an advanced body. They should contain schemes that are good, and practicable in their execution, but quite opposite to what is intended and will really be undertaken: it often happens that the enemy, too credulous, abandons his original designs to pursue chimerical ones, which to him appear very good, and do not present any obstacle to those which the general designs to execute. Prince Eugene succeeded, by this stratagem, in raising the siege of Coni, formed by the French in 1691.

But nevertheless a general should take care that, through a fear of being deceived by supposititious letters, he does not himself too much neglect the intimations which are given him: a general ought, says Onozander, to listen to every body at all times, and upon all occasions. Alexander, when at a great distance from his own country, not being able to receive his couriers till very late, refused to give attention to a peasant, who came to inform him of a shorter route; but soon repenting of what he had done, he sent to seek after him, but in vain.

The same reason that should make a general always have spies in the enemy's army, should also make him suspect that the enemy has some in his; therefore he should endeavour to deceive them, he should keep his intentions secret, mention them to very few, and always talk openly, contrary to what is really designed. Onozander observes, that it shows great folly in a general to mention his designs publicly, especially when they are on the eve of execution; for deserters generally go over to the enemy, at the time an action is unavoidable.

But if it is discovered that the enemy has received information, Vigétius says, that the dispositions must be immediately changed. Polybius, on like occasions, particularly recommends silence and dissimulation; he even stretches this rule as far as the thoughts themselves, which he says must sometimes be repressed, for fear our actions should sometimes betray and discover them. Metellus answered one of his friends, who, on an important occasion, asked him the reason of certain dispositions, "that if his shirt knew what he thought, he would burn it."

To avoid the danger of treachery, sealed orders have been used with great success, which have been sent to officers, with express orders not to open them till at such a time and at such a place: this is an established rule at sea, and can also be practised on shore when employed in an expedition which it is essential to conceal from the enemy.

SECT. II. Of Ambuscades from the Army.

A GENERAL who loses a battle, says Vigétius, may attribute his ill luck to fortune, although these kind of events are generally the effects of art and skill; but he who suffers himself to be surprised, and who falls into the snares laid for him by the enemy, has no excuse to make, because, by his vigilance, and the goodness of his spies, he might have avoided them.

A design should never be formed for an attack upon marches, detachments, convoys, forages, or upon one or many quarters, without knowing the ways which are to be passed, and the places where ambuscades may be formed; whether to avoid, or whether to conceal troops in them, in order to facilitate a retreat, or to draw the enemy into it. A general who receives information from his spies that some enterprises are intended upon some bodies detached from the army, upon one of his convoys, on a forage, or upon his quarters, ought also, on his side, to form ambuscades in the ways leading to it. The number of troops in ambuscade ought to be regulated by that of the detachment intended to be surprised; it should be sufficiently strong to attack the enemy on all sides, that is, in head, flank, and rear. The troops who set out to form an ambuscade should always march by night, unless it be in a country so covered that the enemy cannot perceive them.

A general, according to Santa Cruz, should endeavour to form as many ambuscades as possible; so that, if the enemy should not fall into one, he may not escape the others: they ought to be disposed after such a manner, that one can neither attack or be attacked without being heard, sustained, and assisted by the others: this junction is a stratagem which the enemy could not expect, and which will assure the victory. If, from the fewness of the troops, or the fatigues of the campaign, it is impossible to form many, there should at least be one sufficiently strong to resist the enemy it would attack: but still it is not requisite that it should be as numerous as the enemy, because troops in ambuscade, who charge a detachment that is unprovided on all sides, ought, by this surprise, to have a particular advantage, and consequently supply the place of number; which will certainly be the case, particularly if the enemy falls into the ambuscade during the night, and that care hath been also taken to place a great number of drums and trumpets, that when the troops in ambush charge, they may serve to increase the numbers in appearance, by the terror which noise always raises in the night-time.

In order to deceive the enemy who is in detachment, small bodies should be sent out towards him, with orders to retire to the troops in ambuscade as soon as they meet him.

Ambuscades should always have some object. Before they are undertaken, it should be known whether the enemy is in the field; if he intends either to attack or molest the quarters; whether it is proper to wait for him or to seek him; without these precautions the troops will be fatigued, and no end answered.

Ambuscades may be composed of infantry, hussars, or dragoons; but it is the situation of the country that must determine which. These troops may be mixed together or sent separately; but that must be according to the design intended to be executed, or according to the nature of the troops employed by the enemy in his detachments.

If the design is to attack a convoy, all these troops are necessary, because the effort of it will undoubtedly consist of infantry, cavalry, or dragoons, and also some hussars to clear the march; if a green forage, infantry is very necessary, but it should always be left in the rear to secure the retreat: cavalry, with hussars or dragoons, is sufficient to attack a forage, to beat

the effort of it, or at least to prevent the foraging being executed. If a dry forage is to be attacked, it must be done with infantry, because, as it can only be performed in the villages, it is certain they will be occupied by infantry, and that there will be a chain of cavalry in the front, which will be protected by it: if a detachment, it is according to the nature of the country through which it marches; if an open country, horse, hussars, or dragoons, must be employed; but in a woody or mountainous country, infantry must be made use of. After all that can be said, it is impossible to lay down fixed rules for the kind of troops which should be employed: there are some woody countries where hussars and dragoons can act with ease, and be of great service: there are mountains where they can act securely, because very fine plains, divided by woods, are to be found in the bodies of them, where they can place themselves in ambuscade; but care must be taken to secure their retreat. There are, on the other hand, plains so divided by hollows and canals, that infantry only are capable of acting; therefore it is the general's business to discover from which kind of troops, in either country, he may expect the greatest advantage.

An ambuscade, seasonably and properly formed, may overturn the best concerted enterprise; it is a spring of great resources during the course of a campaign; it is by the assistance of that a general attains the completion of those strokes which are owing to vigilance, and which will never happen when, by a negligence to be condemned, or through pretence of consulting the ease of the troops, they are suffered to linger away their time in camp or in quarters, without being sent out in detachments.

Forethought and activity are the first steps toward great actions; a general endowed with these qualities may accomplish all, or at least a great part of whatever he undertakes. The more difficult an enterprise appears, the more should a general try his genius to find out such expedients as may do honour to the imagination of a great soldier. A general, with a genius and a liking for his business, will find resources on every occasion: want of strength will be supplied by art, and stratagem will prevail over stratagem.

There is no country but presents some place proper for forming ambuscades; hollows, a rotten place, from which it is easy to fall, the least height, woods, hedges, ruins, vineyards, sometimes corn-fields, marshes covered with reeds, all present expedients to a general who knows how to take advantage of them: he must only be careful to place the ambuscades after such a manner that they shall not be discovered by the enemy's parties; and that they are not themselves discovered by the inattention of any of the soldiers, by noise or by other accidents.

If the ambuscade consists of hussars or dragoons, the horses must not be together, their neighings may prove very prejudicial. Even a peasant, attracted by the barking of a dog or the neighing of a horse, may go into a wood, discover an ambuscade, and, often induced by the hope of a reward, will go and give the enemy information of the whole. Every person passing near an ambuscade should be stopped, and that without noise; the peasants should be tied to trees, and guarded by sentries. If the ambuscade is formed in an hollow way, behind an high ground, or in any place.

places whatever, the general must cause every body that is taken to be tied together, and well guarded.

The troops in ambuscade must fall on all parties of the enemy that pass near them, unless when the design is to carry off a convoy or to attack a large detachment. It should in that case continue silent, and let them pass: but if these parties, by making a strict examination, discover the ambuscade, as there can no longer remain any hope of attacking the convoy or detachment, it should fall upon and endeavour to surround them, and, if possible, take them prisoners; and if the troops in ambuscade are so lucky as not to let any of the enemy escape, the ambuscade may remain in its first situation, but always pursue its first object, because here will be no reason to apprehend the enemy's having received intelligence of it.

The troops in ambuscade should attack these parties sword in hand, and not with their fire-arms, and, if possible, prevent them from using theirs. From this manner of attacking, there will result two considerable advantages. The first is, that a brisk and unexpected attack astonishes, and scarcely gives them time to think of their defence. The second is, that, by firing, it is to be feared, that if there are any other parties farther off they will hear it, and send and give notice. It is true, that if those who have heard the firing come to the assistance of the first, and if the troops of the ambuscade find themselves the strongest, this would then be an advantage; but if the enemy's parties should be stronger, the advantage would then turn on their side. Again, should they not come, the enterprise on the convoy or detachment will fail, because there is no doubt, that being sensible of their inferiority, they are gone to seek fresh assistance: in this case, the ambuscade must change situation, and place itself in some other part, but not abandon its original project till the last extremity, and till there is no longer any hope of succeeding otherwise.

The least thing, as has already been said, may be the occasion of an ambuscade's being discovered. The fire of a pipe may be seen at a great distance in the night-time: besides, however small the number of soldiers who smoke may be, the wind may carry the smoke and the smell of the tobacco toward that part where the enemy patrols. The ambuscade should not be cumbered with servants, or any thing else that is unnecessary; orders should be given that the horses are filled with care, and that a profound silence is observed by every body. As it is very difficult for hussars or dragoons to march without leaving marks behind them, by which means the road leading to the ambuscade may be discovered, they should try to enter it by some bye-way, or at least by as dry a one as possible. In order to efface the marks of the horses' feet, eight or ten hussars or dragoons may tie branches of trees to their horses' tails, and, by marching behind the detachment, in as large a front as the whole body, will destroy any marks that are made: as soon as they shall have entered the wood, they will close up the entrance with the same branches, of which they will make a sort of hedge.

If the wood is large, it may be entered at different parts, and the hussars and dragoons may also be made to enter it separately; the footsteps will be more troubling: although the marks which are left by the infantry are not so plain, it may yet practise the same me-

thod of entering the wood. If the detachment intended to form an ambuscade, whether infantry or cavalry, is obliged to march upon a high-way, as soon as it comes near the place appointed, the commanding officer should detach a body on before, with orders to take up the same front as the whole detachment. As soon as it shall have proceeded a quarter or half a league, it will return by another way; and it should also make a large circuit, so that the enemy's parties, coming the same way, will not perceive that they shall be stopped by any troops in that place. This body will rejoin the troops which are in ambuscade, by a road the most out of the enemy's view, never in a body, but scattered, so that they may leave fewer marks behind them. Sentries should be concealed behind bushes, in the front of the ambuscade, so that they may be able to see the country and ways about them, without being seen themselves: two or three soldiers should also be made to climb into trees, in order to see at a great distance, and give notice if they perceive any troops; the same method must be observed with regard to hussars or dragoons.

Before the commanding officer enters the wood where he would form his ambuscade, he should detach two or three patrols to scower it, for fear the enemy should happen to be there in ambuscade himself; after every part has been searched, the troops must enter the wood, and range themselves according to the order that shall have been given them. The commanding officer will form three bodies of his detachment, and place them at a distance one from another; one will be destined to attack the advanced guard, the other the centre, and the last the rear-guard. If the detachment consists of cavalry, the half of each corps should be on horseback; no persons should slip or pass the sentries or vedettes under pain of being declared deserters. During the night, the cavalry should be mounted, and the infantry under arms: in the day-time, half those on foot will relieve those on horseback every three hours; and the same should be done with the vedettes, as well as the infantry and sentries.

If the ambuscade is behind a height or small mountain, sentries must be placed on the top, lying on their bellies, and without hats: in other respects the same dispositions ought to be observed, whether on the march or for the conducting of ambuscades, always paying a proper regard to circumstances and the situation of the country.

There are divers methods of drawing the enemy into ambuscades. The general commanding the army or quarters sends out a detachment under the command of an intelligent officer, to form an ambuscade, at the distance of one or two leagues, more or less, according as the country is fitting for those sort of dispositions, or according to the distance of the enemy. The general must acquaint this officer, that two hours after he is set out, he will send out another detachment, of less force, with orders to go on the side where the enemy is, to endeavour to meet him, and at first sight to make a feint of charging him; but, as if finding him too strong, he will begin his retreat, directing it toward the place where the troops are in ambuscade: furnished with these instructions he will set out.

Then the general will send for the officer intended to command the detachment that is to go in search of the enemy, and inform him of that which is set out to form

form the ambuscade, and of the place where it is; he will order him to advance as near to the enemy as he can, and to draw him by a feigned retreat upon the troops in ambuscade.

These two officers should be the only persons informed of the design: but nevertheless the commandant of the detachment which is to go towards the enemy, may communicate it to the principal officers under his command; so that in case he should be taken or killed in the retreat, he that succeeds in the command may be able to act according to the general's intentions. He must be particularly careful, that no soldier, troopier, hussar, or dragoon, penetrates into the design of the detachment, as it would then be in the power of a single deserter to make the ambuscade miscarry. It may, as has been already said, be composed of different kinds of troops without distinction, or of one sort only: the situation of the country ought to determine whether it should consist of hussars, dragoons, or infantry; but the detachment which is to go and seek the enemy, in order to draw him into the ambuscade, ought to be composed of hussars, unless the country be of such a nature that infantry only is capable of acting.

During the time that the hussars are gone before, endeavouring to draw on the enemy, the troops in ambush will be on horseback, and waiting in silence for their commander's order to go out and charge. As soon as they shall have charged and beaten the enemy, for fear lest another detachment, at a little distance from that which has been beaten, should come to its assistance, they will take the shortest way, and march leisurely, but with order, towards the camp or the quarters. The detachment which drew the enemy into the ambuscade, must form the rear-guard of it, and will march slowly on, while the rest of the troops will retreat, conducting the prisoners with them. If the enemy sends any succours, as soon as the rear guard perceives them, it will double its pace, but with order: there will be no reason to apprehend the enemy's coming too briskly upon it, because he will be fearful of falling into another ambuscade: thus the rear-guard will retreat with ease, and the troops who conduct the prisoners have time enough to reach the camp, without any molestation.

It is on these occasions that a man should know how to keep his courage within proper bounds, and be sensible that flight is glorious: the despair of an enemy that is surprised, and even beaten, is always to be feared, when he is not entirely defeated. A man should always be content with one victory, without attempting a second: he may, by pursuing the enemy too eagerly, fall himself into ambuscades more dangerous than that he has just drawn the enemy into.

Robert, count of Artois, having discovered a ford, obtained permission of St Louis to pass it, in order to facilitate the passage of the Christian army, with a promise of undertaking nothing till such time as it should be passed. He passed it safely; but, contrary to his word, he threw himself with eagerness upon a detachment of 300 Saracens, who fled before him. Carried away by his courage, he followed them to their entrenchments, which he forced; and, not being content with this success, more glittering than solid, he still pursued them to a ruin which he saw open: he en-

gaged himself in it, contrary to all the remonstrances of the most intelligent generals of the army; he entered, followed by his soldiers, who at length, busied in plundering, were charged in their turn by the Infidels, who had rallied. In short, the count of Artois, the generals who had not been able to stop him, the Hospitallers, and the Templars, who accompanied him, perished on that unfortunate attempt; a loss which was the cause of the taking of St Louis, brother to the count, and of the calamities which the Croisies sustained in that campaign.

If there is reason to apprehend that the enemy, having notice from some deserters, are coming in full strength, the ambuscade must then change its situation and draw nearer to the place from whence it set out: so that, if the enemy should be stronger than the ambuscade, it will have less way to retreat, because it is certain that he will march cautiously; that he will not go towards an ambuscade which he knows to be formed, but with design to attack; and his superiority cannot but prove fatal to the troops forming the ambuscade.

It may again happen that the enemy, not finding the ambuscade in the places pointed out by the deserters, will imagine it to be retired, and, in that belief, will neglect the precautions necessary in such a situation. In this case, the detachment must change place and post itself a quarter of a league, at most, from where it first was, in order to fall upon the enemy, who will march on with confidence: but the detachment in ambuscade should be sufficiently strong, to be at least able to retreat before the enemy, if he is superior, and support itself by its own strength. Detachments of 1000 men have been often known to retire in order from before others of double or treble their number, which undoubtedly proceeds from the advantageous positions which the commander has known how to take; from the disposition he has made of his troops; the order he has established among them; and from the resolution with which he has inspired them: with these qualities, a commander may at least be certain that his troops will not be beaten, although they do not get the better, unless by a force so much superior, as to prevail over courage and a wise and judicious conduct.

An ambuscade that is successful, may cause the destruction of a whole army. The example cited by M. de Feuquieres, in his Memoirs, on that head, is striking. M. de Luxembourg, still attached to the prince, took all the baggage belonging to M. Turenne's army, because the lieutenant-general who commanded the escort did not foresee that the enemy, shut up in his lines of circumvallation before Arras, having two armies near his camp with a design of attacking him in his lines, could think of sending out a large detachment of cavalry on an enterprise of such a sort. In the mean time M. Luxembourg, who was in ambuscade, within reach of the column of baggage, seeing that the lieutenant-general was gone on before with the head of the escort, imagining the baggage in security, marched speedily to the head of that column, whole march he stopped, and turned toward St Pol, where he concluded the whole baggage belonging to M. Turenne's army, without his knowing any thing of the matter. It is thus that, by the negligence of an officer, and by an ambuscade seasonably placed, an army finds

finds itself stripped of all its baggage, and, as may be said, not in a condition of continuing the campaign.

If this lieutenant-general had been provided with spies, detachments in front and on the flanks, these detachments would have discovered the ambuscades, and, by the precautions usual on such occasions, he would have placed the baggage of the army in safety. Again, his spies would have given him notice, that a large body of cavalry was detached from the camp before Arras, consequently he would have been upon his guard; instead of which, being full of a false confidence, he marched as if in a champaign country, and, by this unpardonable remissness, occasioned the loss of the whole baggage.

An officer who commands a detachment for any expedition whatever, cannot possibly take too much care to foresee the checks that may happen to him; if he is beaten, it should be wholly owing to a superiority of force. He who, after having taken all the precautions possible, is beaten by an enemy who has the advantage of number, has nothing to reproach himself with: but he who, with ability, has nevertheless neglected certain precautions, and is beat because they were not taken, is certainly culpable in the eyes of intelligent men. But if this check induces him to neglect nothing necessary to the avoiding of a second, he cannot pass for a bad officer; that appellation is only applicable to him who, suffering himself to be blinded by conceit, or the false lights which self-love makes him take for the effects of a superior genius, suffers the enemy to obtain an easy victory.

A general overcome, as Pompey was at Pharsalia, is not the less deserving of laurels and statues, provided that he does not suffer himself to be discouraged, like that great man, after his defeat: but he who is beaten like Antony at Actium, raises compassion of none but a freed man or a mistress.

Misfortune is an addition to the glory of an illustrious soldier, when he knows how to derive instruction from it for the future. The marshal de Créquy, before losing the battle of Conarbrick, was a great general; afterwards, he was a great man. This was the judgement formed of him by the great Condé, who notwithstanding did not love M. de Créquy: "Sire, (says he to Lewis XIV.) your majesty has just acquired the greatest man that ever professed the science of war."

SECT. III. *Of Camps in offensive War.*

To take an advantageous position for an army; to make choice of a spot that by its situation is strongly secured; to establish a camp there, and to be also able to have the army within distance of marching easily to the enemy, without fear of being molested; in short, to throw such difficulties in the enemy's way as may prevent his harassing the army, is one of the most essential branches of knowledge for a general. He who is endowed with this talent can, with an inferior army, not only make head against, but also cause his enemy's designs to miscarry; fatigue him the whole campaign by marches and counter-marches, which lead to nothing; oblige him to remain inactive, and at length draw him into a favourable position, where he will be morally sure of beating him; as was done by Mr Turenne in 1675, who, after having exhausted every expedient wherewith his military knowledge

could furnish him to draw M. de Montécuculli into a disadvantageous post, at length succeeded, found an opportunity of attacking him, and gloriously fell at the instant victory declared itself in his favour.

Before a general takes the field, he ought to be very certain what number of troops he shall have, that his magazines both of war and provision are ready, as well as the waggons, pontoons, and all other implements whatever that are necessary for an army; for events may happen that it is almost impossible to foresee, and which often alter the best concerted designs. There have been instances of generals who, having taken the field with an intention of acting offensively, have been obliged to change their plan to the defensive; because the magazines which they had ordered, have, through the negligence of those intrusted with the care of them, not been collected; or because the army has been weakened by detachments necessarily sent from it, either to the assistance of allies, or to some towns threatened by the enemy: by such kinds of accidents the plan of a campaign is entirely destroyed.

But let it be supposed that the general has the troops necessary for acting on the offensive, or that the events of the foregoing campaigns force the enemy to keep on the defensive; that the heavy artillery, the field-pieces, and the carriages of all sorts, are ready to march; that the magazines are filled, and the roads free and safe; that the pontoons and the boats got together, either for the passing of the troops, or the transporting the provision, in case the country should be divided by rivers; then a general possessed of the necessary talents, can foresee the event even before taking the field: he will know beforehand the marches he is to make, the camps he is to occupy, and those which the enemy will endeavour to seize in order to oppose his designs.

An offensive war is undoubtedly carried on with greater ease in an open, than in a mountainous country. In plains an army acts openly, forage is in greater abundance, the provisions can be conveniently transported from one place to another, and the marches are performed with more ease. Among mountains, he who is best acquainted with the country, who has a head fraught with expedients, and is the most vigilant, hath often the advantage, although inferior in numbers; at least he maintains himself in and preserves the posts of which he is in possession with greater ease; and an attention to seize such advantages as the ground offers will put such a general upon an equality with his adversary.

But whether in an open or in a mountainous country, and however superior the army be to the enemy's, the least negligence in the choice of situation may render the superiority of troops useless, and even hurtful: useless, if, from a desire of taking up too much ground, the enemy is so divided that the enemy may fall either upon the right or left without a possibility of its receiving succour; hurtful, if, from a desire of assembling the army in too narrow a spot, the troops too close together are unable to act without embarrassment to each other. This superiority should not cause a general to be neglectful of the safety of his troops in their camp; he should always be assiduous in preserving the strictest order and discipline among them; one or two checks are generally sufficient to discourage the soldier, and take away that confidence which he ought to have in

Defensive Operations. his general: the advanced posts should be well guarded, the flanks secured, and detachments frequently sent out towards the enemy; for as success is insured by vigilance and care, for negligence and slack discipline are ruin to the most formidable army, and entertaining a contemptible opinion of an enemy renders him more daring.

Whatever situation the army is in, it ought always to avoid presenting a flank to the enemy, and should also use every endeavour to take a camp in a situation that is naturally strong; the wings should be sheltered, and every part both before and behind should be covered by detachments: but whatever the nature of the country is, an army should never fix upon a camp where there is not wood, water, and forage, within reach.

It is to be observed, that a camp ought never to be fixed on the banks of rivers; but a sufficient space should always be left between them and the camp, to draw out the army in order of battle. If this precaution is not taken, it may happen that the enemy, encamped either near to or at a distance from the other side of the river, being informed of the position of the army, will come in the night to alarm the camp, and by a discharge of artillery and small arms throw the whole camp into confusion, without risking the loss of a single man: but again, by encamping an army upon the banks of rivers, how will there be a possibility of drawing it out in order of battle, or posting advanced guards? For these reasons, a camp should always be placed at least eight or ten hundred yards from a river; so that the guards may be advanced without being exposed, and within the circumference of the camp and compass of the guards the army may be supplied with forage for at least four days, and more if possible.

There are some situations for a camp which are in appearance strong, but may notwithstanding prove very dangerous, if care be not taken to examine whether or not the army can with ease come out of it, to form itself in order of battle; or whether the enemy can prevent it, by blocking up the avenues and outlets. If this precaution be not taken, an army may be the means of shutting itself up; as was done at Senefé in 1674, and by the allies at Alschaffenbourg in 1743.

If the war is carried on in a woody country, the same precautions must be used for the security of the camp; but the dispositions must be changed according to the nature of the country: there is scarcely any country so entirely woody but has some plains in it. The choice and strength of a camp depend on the position of the enemy and situation of the country: a general should always avoid encamping the cavalry in a wood, and should be particularly careful that the wings are sheltered; the woods should be occupied by the infantry, and entrenchments thrown up in front, according to the designs intended to be put in execution. If the wings are sheltered by a village, it should be entrenched, and infantry posted in it; and the camp should be covered by a river as much as possible, unless the intention is to march towards the enemy; then all the obstacles that can prevent the army coming up with him should be avoided: but if, from some success of the enemy, or from his superiority of troops, the general cannot determine upon opening the campaign offensively, he must use other

means to bring it about; and in the mean time should strengthen himself in his camp, establish posts on the banks of the river, and cover them by continual detachments of light horse, who, by extending themselves, will prevent parties of the enemy from passing to seize on the hind-parts of the camp, molest the convoys, and attack the foragers. If there are woods at a small distance from the camp, posts of infantry must be established in them. Guards of cavalry are never advantageously posted but in a plain; but if there should be any space between two woods where cavalry can act, and from whence it can take surveys at a great distance, a guard of cavalry should be placed there; but posts of infantry should be placed in the woods to protect it, and to which it may retire in case it is attacked.

Whatever may be the nature of the country, it is often necessary to have corps detached from the body of the army, to cover or keep open a communication with some place, in order to prevent the enemy from foraging too near the camp; to preserve the forage; to raise contributions at a distance; to occupy some advantageous post; to oblige the enemy to divide his forces in order to oppose that body; to cover the camp either in the front or on the flanks, according to that side which is left most unguarded and exposed: in a word, there should always be continual detachments toward the enemy, as hath been the practice of many generals, and of marshal Saxe in the late war. The strength of this body is to be proportioned to the use designed for it by the general; but it is usually composed of light horse, some regiments of light infantry, and a brigade or two of dragoons. In the end will be seen what use should be made of this body; but in whatever situation it is to be placed, the communication between it and the army must always be kept open, that it may always be able to join it on the first order; and its camp must be so chosen, that the general may always receive intelligence from it of the least movements made by the enemy. See Plate CCXCI.

If the war is carried on in a mountainous country, there are generally some small plains or valleys where an army may be encamped, if not altogether, at least some part of it: besides, in these sort of countries a general is almost always obliged to separate his troops; to send out many detachments in order to guard the passes and communications between each other; to endeavour to out-flank the enemy, or for such like dispositions; so that the army not being all together, it must be discerned where to fix the most considerable body.

A general who carries on war in a mountainous country, and who by the superiority of his army is enabled to act offensively, ought to endeavour by the positions which he takes to surround the enemy; to render his foraging difficult; to harass him by continual small detachments, which the enemy will be forced to oppose by others more considerable: he should endeavour to steal a march of him; and although a general should never expect success from the enemy's negligence, there have nevertheless been seen instances where armies, by activity and dispatch, have gained a march or two on their enemies, although commanded by able generals.

If the enemy's vigilance prevents the general from suc-

Offensive Operations.

succeeding, he must employ new stratagems, and never give up his point; he should try all those that lead to the same end, although by different channels; either attacking some detached posts, oblige the enemy to send succours to it, and by that means weakening other places which he should endeavour to force; or decamping, and feigning to penetrate on some other side, to oblige the enemy to abandon a camp that is advantageously posted, and by that means to draw him into some post that is weaker either from situation or from the extent of country he is obliged to defend; and by this method find an opportunity of attacking him with advantage.

In short, in whatever country, and on whatever occasion, a camp is always defective if the wings are not sheltered, or are to be easily distressed by the enemy; if the front is not guarded and the rear well covered; if the communications with the frontier-towns are not secure and easy; if there is any want of forage, wood, and water; and if there are not detachments in front, to prevent the enemy from approaching the camp.

A general who joins experience and study together, ought to see into the intention of the enemy's general, and judge of his designs by any of his proceedings, however trifling.

All those who are destined to the command of armies cannot be endowed with this quick and exact eye, that ready power of judging of a good motion or a good position upon the spot. Some generals have excelled in marches, others in the position of camps; these in the arrangement of troops in order of battle, those in their conduct in time of action; others in providing subsistence; others in projecting a campaign. There have nevertheless been some of these great men, whose genius and temper have united and carried these qualifications to the greatest degree of perfection; but the rarer these examples are, the more a man ought, by continual study, to endeavour to augment their number, and strive to merit the honour of being enrolled among those heroes, the ornament of mankind, their country's support, and their master's glory.

SECT. IV. *Of the Attack of an Army on its March.*

HOWEVER difficult certain operations in war may appear, they are nevertheless not impracticable when a general knows how to take the necessary precautions for softening those difficulties. The attack of an army on its march seems to be above all reach of attempting; whereas the success of such an attempt depends only upon knowing how to take proper measures, on choosing the ground, and of seizing a favourable opportunity. It seems more difficult to surprise an army on its march, than to attack it openly: the number of the enemy's troops; the precautions which their general shall have taken, the order, the care, the secrecy which must be observed, present obstacles almost insurmountable; but yet, by taking the bye-roads, by concealing his march from the enemy, a general may attack him in force in the rear or upon the flank, at the same time that he causes his advanced guard to be attacked by some infantry, cavalry, and even cannon, to make him the less suspicious that the attack upon the flank is the real one.

When an army would attack another upon its march, it should endeavour to be beforehand with it, and, by

the means of stolen marches, come up with it before it can know any thing of the matter: some parties should be detached, who must place themselves in ambuscade, in order to stop all the comers and goers, so that the march and designs of the army may be kept secret from the enemy. Whenever a general hath determined to attack his enemy, he should send off all the baggage, both great or small, belonging to the army; and it should be left in the rear under a good escort, near enough to join after victory, without the army's being obliged to wait three or four days for it.

The general should be well assured of the day on which the enemy's army sets out; of the country through which it is to march; whether it is an open, mountainous, or woody country; if it is divided by rivers; whether there are many bridges to pass; and in how many columns it marches: he should also get all possible information of the disposition of it. In the third section of the first part, relative to the march of an army in an open country, the disposition which it ought to make, in case it presents its front or flank to the enemy, hath been laid down. The general designing to attack ought to regulate his dispositions by those which the enemy hath taken, and which he can only know from his spies; but if the general cannot receive any information concerning them, the best rule for him is to suppose them good, and to form his own accordingly; it would be very imprudent of a general to suppose his enemy's dispositions are bad, when there is no danger in supposing them to be good, and acting in consequence of that supposition.

A general may march his army in six, eight, or ten columns, as the nature of the country will allow; they should arrive at the place appointed at the same time. The nearer the army is to the enemy, the brisker the attack should be; because the columns having less way to go, the enemy will have less time to make his dispositions.

As in the case of a surprise there cannot be signals given, without running the risk of the enemy's discovering that he is going to be attacked; it is therefore necessary, that every general officer leading columns should have a watch, regulated by the general's, so as to march all at the same time, at the hour agreed on and ordered. The ancients, destitute of watches, regulated their motions by the course of the stars; and it is, without doubt, on that account that Polybius, Ono-zander, Elian, and many others, exhorted military men to the study of astronomy: but as it is not often that an army marches by night, this knowledge would be very useless for an attack in the day-time; besides, the sun, by which they were also regulated, could be no way serviceable to them, should the sky be overcast.

If the general's intention is to attack the enemy's army in front, he must detach all his light troops, sustained by a large body of cavalry and some battalions, with orders to harass the flanks, in order to perplex the enemy with regard to the real attack. It is impossible to give the enemy too many false alarms with regard to what is really designed: the hussars, from their readiness in retreating, and their quickness in passing from one spot to another, are the fittest troops for these sort of expeditions. The same rule ought to be observed if the real attack is designed to be upon the flank; then the false attacks should be upon the front.

Offensive
operations.Offensive
Operations.

fronte. In Santa Cruz may be seen the dispositions which he has made to attack an army on its march.

Stratagem, and the means of surprising an army, are allowable in war, provided treachery is avoided. Whilst the law of nations is not infringed, successful stratagems add lustre to the genius of the general: however irreproachable the conduct of Scipio Africanus might be, the means made use of by him to surprise the army of Syphax are by no means to be approved of.

The Roman general amused the Numidian king with feigned propositions of peace, during which time he had his camp reconnoitred by officers, disguised like slaves, belonging to the train of the Roman ambassadors. There is no profession where a rectitude of mind is more necessary: a real soldier scorns to act by indirect methods; he abhors deceit, and considers treason as belonging only to mean spirits.

Attilius, after the battle of Cannæ, came to Fabius, and offered to deliver Arpi up to him, which he had formerly delivered up to Hannibal. Fabius having carried this proposal to the senate, they debated whether they should put Attilius to death as a runaway, who was neither a friend to the Romans nor an enemy to the Carthaginians, and whose fidelity fluctuated according to the changes of fortune. Hannibal afterwards put the wife and children of this traitor to death.

Orozander observes, that promise and faith should be kept even with traitors: a man may keep his word with them, and have nothing to fear, provided he knows how to mistrust them. The difference between stratagem and treason is very great; the one a man may guard against, but no degree of human prudence is sufficient to shield him from the other. When, as related by Virgil, by the contrivance of Sinon, the Trojans themselves introduced the enemy within their walls, they could cast the blame only upon their own imprudence and credulity; but when, in the Iliad, Minerva is seen, in contempt of a sworn alliance, persuading Pandarus to shoot an arrow at Menelaus, one is apt to wonder how Homer dared to intitle Minerva, The Goddess of Wisdom.

In order to carry on a surprise by stratagem, one of the most certain methods is, to calculate what time is necessary for the army to arrive at day-break near the road by which the enemy is to pass, so as to be able to examine the country, and make the necessary dispositions for the attack: in an open country the army may be concealed behind corn, or behind a rising ground.

Prince Eugene, in 1702, after the battle of Crostolo, having gained some days march of the king of Spain, posted himself between the Zero and the Po. He so well concealed his army behind the bank of the Zero, that the combined army of France and Spain, which was on its march, and ready to enter into its camp, was obliged to range itself in order of battle, and to fight, without having scarcely time to make any disposition; and had it not been for those, which had been wisely foreseen by the king of Spain and M. de Vendôme, it is probable the combined army had been beaten.

A woody country offers more expedients for the concealing of troops: but as it is to be supposed the enemy's advanced guard will be advanced at least half

or three quarters of a league, to sower the country; therefore, if the general's design is to attack the enemy's flank, he must present some cavalry and hussars in the front of the enemy's army, so as to engage his attention. Some infantry should be placed in the woods, in the rear of these troops, in order to sustain them: this cavalry and the hussars should retire in proportion as the advanced guard advances, in order to induce the enemy to believe they are not sufficiently strong, and that the reason of their advancing was only to examine the march of the army. As soon as the enemy shall have reached the place agreed on by the generals leading columns that are to attack, the body of infantry that is in ambuscade in the wood, the number of whose columns should be regulated according to the situation of the country, will march silently, and near enough to the enemy, and will charge him with bayonets, without giving him time to recover himself: during this attack the cavalry, dragoons, and hussars, who keep the enemy's front in awe, will charge the troops who have passed the wood and spread themselves over the plain. These troops of cavalry must be sustained by the infantry which was in their rear in the wood, and which should be furnished with cannon. These two attacks, made one after the other, but at some small distance of time, will render the enemy doubtful with regard to the dispositions he is to make; he will be undetermined where to send assistance, as the cannon which he will hear at the head will induce him to believe that attack the real one: he will fly to that part, and will consequently weaken the flank, which is designed to be attacked by all the infantry. By this diversion the flank will with greater ease be broken through, and the enemy taken in rear: the enemy thus surrounded, and finding himself between two fires, cannot avoid being beaten.

It is more difficult to form ambuscades in an open country, particularly for a whole army, unless it should find a bank like that at Zero; then the general should consider whether or not the attack of the army on its march is practicable. If the general by his superiority can, without weakening himself, divide his army, and find means to conceal it, he will attempt the attack, provided that each detached body is posted before the enemy has begun his march, and that they can all join on the first order, without a possibility of being cut off or finding any obstacle to prevent their marching up to the enemy: but, in order for a greater certainty of success, these first dispositions being made, great exactness in giving, and diligence in the execution of the orders, is necessary; each separate body should charge at the same time, and at different parts. But as it may happen the attack may prove unsuccessful, whether owing to the good disposition of the enemy, or whether because the attacks were not made together or executed with equal vivacity, it is necessary that the general should have provided for a retreat, and that the officers commanding different bodies should know after what manner and from what part it is to begin. For the greater security, the general officers ought to communicate their instructions to the commanding officer of each body composing that which they command, so that at the time of the attack or of the retreat, they may instantly comprehend the meaning of whatever they are ordered to perform.

If the army intending to attack the enemy on his march is weaker, or equal, either in number or in the nature of the troops, it is then only the situation of the country, and the facility with which the enemy may be surpris'd, that should determine the attempt of this grand enterprize: the prudence of the general, his experience; that of the generals who are under his command; the quality of his troops; whether they are well disciplined or not; whether they are composed of one or of many nations; the quality of the troops to be attacked; and, in short, the genius of their general, are circumstances by which the attacking or not attacking should be decided. It is impossible to be decisive upon these circumstances, which depend entirely upon the ground, upon the vigilance of the enemy's general, upon the order which he causes his troops to observe in their march, and in short upon the troops under his command. A general, at the head of a well-disciplined army, composed of veterans and good general officers, will undertake and execute designs which he would not even dare think of with a new-raised army, however numerous: it is also very difficult to surpris'e a vigilant general, who is besides a good soldier, and who is also assisted by the counsels of able and intelligent officers.

A general should also be guided, in attacking the enemy on a march, by the country and the nature of the troops of which his army is composed. If the enemy marches through an open country, and the general is equal to him in infantry but superior in cavalry, he should make no hesitation in attacking him; but if the country is woody or mountainous, and the enemy's army is more numerous in cavalry than infantry, the general has still the same advantage with a superiority of infantry; because the enemy's cavalry, in those kind of countries, is unable to act against infantry; and the infantry also which the enemy may have will never be sufficiently strong to maintain itself upon the heights against forces so superior: and if the heights are forced, there can be no doubt of the enemy's being beaten, of his cavalry being ruined and crushed to pieces, or that his retreat will be attended with great difficulty, and that he will lose the greater part, if not the whole, of his army.

It is true, that an army so weak in infantry and strong in cavalry rarely engages itself in a woody or mountainous country; but it may happen that the enemy is obliged to pass through these countries in order to transport the feat of war to a spot more favourable for the cavalry. On this occasion the general must endeavour to concert his measures after such a manner as to render it impossible for the enemy to molest him, to dispute any pass with him, or to attack him on his march; if a general on any occasion engages himself rashly, it is a mark both of imprudence and want of capacity. If Amilcar Barca had engaged himself in the streight of Hache with a greater number of cavalry than infantry, he would never have been able to overcome the African rebels, whose chief strength consisted in infantry. Hannibal would not have engaged himself in the Alps without being much more numerous in infantry than cavalry; and yet the difficulty which he found in that passage was more owing to the trouble caused by the cavalry and baggage, than by the mountaineers, by whom he was conti-

nually harassed.

In a word, the attack of an army on its march should be foreseen beforehand. This operation requires the agreement of many circumstances, an inviolable secrecy and an exact knowledge of the country: a plan should be laid relative to the precautions the enemy may be supposed to take in his march, as well as those necessary to be taken to steal marches of the enemy, to approach him in order, and for observing strict silence in the march. The general should also endeavour by all means to gain the inhabitants of the country over to him, to choose a spot where he can march under cover, without which he can march only by night; in which case it will be difficult to prevent some of the columns from straggling, which will be sufficient to cause the miscarriage of the enterprize. The general should have safe and intelligent guides, be certain of his troops, and have nothing to apprehend from deserters; one of which is enough to baffle the best-concerted measures. In 1693, prince Eugene, on receiving intelligence that the Turks had prepared a large convoy for the garrison of Temeswar, formed the design of carrying it off: he therefore put himself at the head of the detachment destined for the execution of this design; but a soldier who deserted to the enemy prevented the Turks from marching, and the prince was therefore obliged to return without accomplishing his design.

SECT. V. *Of the Attack of entrenched Camps.*

THE principles of war among all nations and in all times have been still the same; but the little experience of the early ages of the world would not permit those principles to unfold themselves, as they have since done, and to which it is owing that new expedients both for attack and defence have been discovered.

In the fabulous times of Greece, the first conquerors were esteemed as gods, because they, by their genius and valour supplying the want of art, were regarded as beings superior to humanity, as mortals born for its destruction; but now, as arts of all kinds, and particularly the art of war, have soared to a pitch of almost perfection, these gods of antiquity are no longer considered in any other light than as great men who made themselves superior to the rest of their contemporaries. In proportion as posterity hath become more enlightened, it hath also become more just; it hath preferred the title of hero for those who have not made an ill use of their superior talents and strength; but hath given the detestable name of tyrants to those whose desire of revenge and rage have outlived their success.

The first epocha wherein the military talent became conspicuous, is the siege of Troy, although there were even wars prior to that. Homer, when describing the shield of Achilles, mentions wars raised for the carrying off cattle. Horace confirms this; and in his Satires also mentions a war anterior to that of Troy, the occasion of which was the same, and without mixing sacred authority with these profane ones: and those who know the passions can want no arguments to convince them that men have been in a state of warfare from the time they have been actuated by them, or, to use a better expression, as soon as mankind was formed into society. Even before the siege of Troy, Hercules

and

and Theseus had already astonished the Greeks by their conquests; but although these two heroes have purged the world of many flagitious men, their victories are rather a proof of their strength and cunning, than of their knowledge in the military science. In proportion as Greece became polished by the laws of Lycurgus, the people, more enlightened, discovered, in the necessity of self-defence, the principles of attack. The Grecians gave birth to that science which the Romans extended, which succeeding ages improved, and which we have almost brought to perfection.

What a sensible difference is there in the military art, such as it at present is, compared with that of which the rules are handed down to us by Onozander, Vegetius, the emperor Leo, Frontinus, Ælian, and many others? The towns, in their times, had no other defence than walls, raised at a great charge, flanked at little distances with towers, and a large ditch in front: it is true that the little force of their weapons contributed much to the advantages of their fortifications. Their entrenched camps had only a large ditch with some waggons placed behind it; and whenever the ancients were willing to practise all the art at that time known in war, they surrounded the camp with walls, in the same manner as they did their towns, with towers at little distances. Of this kind was Pompey's camp at Dyrachium in Epirus, the plan of which is given in the *marshal de Puysegur's Art of War*: the wall by which it was surrounded was 15,000 paces in extent.

The emperor Leo was unacquainted with any other method of entrenching a camp, than by heaping fascines together, putting trees upon one another, and posting advanced guards.

The experience which hath been since acquired, hath, without abridging the labour, rendered the works of places stronger, and easier to be defended: the labour of the entrenchments for camps hath been shortened; they have taken a new form; and being constructed upon the same principles as the fortifications of towns, they are become more difficult to be forced. By this same experience the means of attacking them hath been discovered; and in proportion as offensive weapons have changed, and are become more powerful, the system of fortification has been new-modelled.

The power and force of arms being become more considerable, it has been thought necessary to oppose them by such fortifications as were capable of resisting them; and necessity has done that which genius was till then unable to effect. It is for this reason that in the latter wars, and in those of the present time, generals have not been contented with making ditches in the front of their camps in order to entrench them, after the manner of the Romans, but have to them added lines, angles, and redoubts, at proper distances. Art hath been carried yet farther, by the addition of walls in front of the ditch: in short, M. Saxe, in the last war, instead of making use of lines to entrench his camp before Maeltricht, only caused redoubts to be erected at proper distances, each of which had a covered way which was palisaded, and the redoubt fraized; and he also caused large and deep wells to be sunk in the ditch. Our posterity may perhaps discover something to add to the strength of these entrenchments; the

knowledge of a succeeding age being always increased by that of the preceding.

A general should be determined upon the attack, and the manner of it, by the nature of the entrenchments and the situation of the country. Such entrenchments as those of M. Saxe at Maeltricht, are very difficult to be forced; nor can the design of it be formed without great superiority of force: even then the success is uncertain. The strength of these entrenchments hath been seen in the sixth section of the first part.

But a camp entrenched with lines may be attacked; although, at the siege of Philippsburg, Prince Eugene at the head of 80,000 men, did not dare attack those which were erected by the duke of Berwick: but this example should not serve as a rule. Two great men naturally fear and respect each other: Prince Eugene being thoroughly acquainted with the duke of Berwick's ability, was therefore convinced that his rival had taken all those precautions which he himself would have done in the same situation: the duke of Berwick, doing the same justice which all Europe did to Prince Eugene's talents, had to the prudence of his dispositions added all the assistance of art. The prince having examined the lines, and finding them strong in every part, acted the part of a wise and experienced man; the lines were not attacked, and Philippsburg was taken.

Camps entrenched with lines are not always equally strong in every part; they are neither always commanded, nor even to be attacked, by generals equal in talents, capacity, and experience: and when they are, there are some occasions where force and resolution must be joined to the prudence of the dispositions.

Let an army be supposed entrenched behind lines where art and nature are both joined; whose flanks are sustained and secured, furnished with troops and artillery along the whole front, with more troops behind to sustain those which line the lines. The general who would attack, ought first to survey the situation of the lines himself, and as much as possible the enemy's disposition; he will examine the construction of the lines, how they are supported, their extent, and whether the soil is firm or light. As soon as he shall be perfectly acquainted with these circumstances, he may form his plan of attack, and cause his army to march in as many columns as there are attacks to be made; but he should endeavour as much as possible to occupy the whole front of the enemy, whether for the strength, or whether to prevent the enemy from sending assistance to those places where the attack will be briskest. The head of each column should be well furnished with artillery; and as soon as it shall be within distance of cannonading the lines with effect, it should keep up a brisk and continual fire for the space of an hour at least, so as to beat down the earth of the parapet, and tumble it into the ditch, which will in some measure render the passage of it less difficult for the troops. The time of the attack should be an hour before day, so that the cannon may have fired before the enemy shall know where to direct his artillery: after every discharge, the situation of the cannon should be changed either to the right or the left, in order to deceive the enemy's gunners, and prevent their knowing where to direct their pieces. If there should be
any

any height within proper distance, the cannon should be planted upon it: if the cannon can be brought to cross each other upon the lines, the artillery will then have a very great effect.

The infantry should follow the artillery, furnished with hurdles, planks, fascines, pick-axes, and shovels; the fascines will serve to fill up the wells, if there are any, before the ditch; or if there are no wells, they will fill up the ditch, and the hurdles will be thrown over them. The cavalry should be formed in two lines in the rear of the infantry, in order to sustain it. The general should endeavour to find some ridges, to conceal the cavalry from the enemy; but should there be none, it must be placed at such a distance, as not to be exposed to the cannon of the lines; for should it be placed too near, it will very soon be destroyed, without having it in its power to be of any service; the great fire which it will sustain, may strike it with terror, which may cause it to give back, and discourage the infantry, or at least deprive it of that resolution and vivacity which it had, knowing itself to be sustained; besides, it is great inhumanity in a general to expose troops which he can place in security. The enemy appears less formidable when force can be opposed by force; but the bravest soldier will be often disheartened when he sees himself exposed to blows which he has not in his power to return. Besides, as in the beginning of an attack of lines, the cavalry cannot be of any assistance, and cannot act till the infantry hath penetrated in some part, it would be useless to cause it to advance too near, provided it is within reach of marching readily when the infantry has passed, and hath made a passage large enough for it, by beating down the lines and filling up the ditch; the cavalry then will have no more to fear from the cannon of the lines, because the enemy's attention will be more engaged with endeavouring to repulse the infantry, than with firing upon the cavalry. As soon as the lines have been sufficiently cannonaded to beat them down, and throw the enemy into confusion, the infantry should march resolutely and together; and should take care to leave room for the artillery, so that it may advance at the same time, and continue its fire. The attack should be made by the grenadiers, sustained by the piquets: they will protect the soldiers who fill up the wells and the ditch; and as soon as they find an opportunity of passing, they will endeavour to get over the entrenchments, sustained by the whole infantry of the column, which will then be disencumbered of the fascines, hurdles, &c. in order to drive the enemy from his lines. As soon as there are soldiers enough upon the lines to bear the resistance of the enemy, the soldiers who have the shovels and pick-axes, and who ought to be last, will finish the filling up of the ditch by beating down the parapet of the lines, and making an opening sufficient for the passage of a squadron in order of battle. Then the whole infantry of the column that has broke through, will pass and divide into two parts, to let the cavalry pass, which will form under the cover of the fire of the infantry, and will not attack the enemy's cavalry till it shall have collected its whole force together.

If one of the attacks succeeds, on the first news, which will soon be spread throughout the army, all the troops at that time ought briskly to attack the whole

front of the line, in order to employ the enemy, and prevent his sending assistance to that part that is forced. The reserve, which is composed of infantry and cavalry, ought to join the troops that have broke thro' the lines, to sustain the cavalry charging that of the enemy, and cannot be sustained by the infantry who passed the first, because it is employed in taking the enemy in flank to the right and left. In this situation, when the reserve and all the cavalry which followed the column that hath passed, and to which others may yet be joined shall have passed, it should attack the enemy; if it is repulsed, it can never be to any great distance, because it has infantry behind it, to sustain it, and by its fire to stop the enemy. If the lines are forced by many columns, the success and also the defeat of the enemy will be thereby rendered more certain.

This disposition appears to be good, because the lines having been partly destroyed by the cannon, because the enemy cannot but have lost a great number of men, and because part of his artillery has been dismounted, without the army that attacks having sustained much loss. The prince of Orange in 1639, being posted upon the Ghete, at Nerveinde, entrenched his army after such a manner that it could not be surrounded; his right was supported by a river, and his left by the village of Romdorff, bordering upon the rivulet of Landen. M. de Luxembourg, being willing to attack him, could only get up with his cavalry in the evening, his infantry and cannon not being able to come up till night: that general during this time formed his disposition, and between five and six in the morning he put his army in motion, which formed in order of battle as it marched along, the infantry and cannon in front, and the cavalry in the rear.

When the duke of Savoy and prince Eugene, still encamped between the town of Pianezza and la Venerie, in 1706, marched to attack the lines of the French army that besieged Turin, they caused their armies to march in eight columns; the infantry formed the advanced guard, the artillery, distributed by brigades, marched at the head between the columns, the cavalry was behind in six, and out of reach of cannon-shot.

The disposition of marshal de Coigny in 1744, in order to attack the lines of Wissembourg, of which the enemy were in possession, was like it, except that the whole of his army had not time to get up; but as the moments were precious, he did not wait for it. The army which came from Landau divided itself into four, which formed the four attacks; one of which was at Wissembourg, the other at the mill between that town and the village of Picards, the third at the village of Picards, and the last was made above that village, which was entrusted to the Hessian troops. His cavalry, which was behind, passed after the infantry had broke through the lines; but the enemy were then almost either killed or taken, and those who could save themselves, retired to Lautrebourg, where their army had assembled after having passed the Rhine. It is difficult to determine which is most to be admired, whether the general's disposition, the quickness and exactness of his eye, and his coolness in a circumstance so delicate, or the courage of the French troops, who forced these lines in less than two hours.

As soon as the enemy is beat and abandons his lines, he must be pursued, but with precaution. The vivacity
with

with which he should be pursued, depends upon the order with which he retires: if it is an open country, the general may follow him so long as he sees all clear before him; but if the country is divided with defiles and woods, it would by no means be prudent for him to engage himself in them, for fear of any ambuscades being placed there by the enemy, in order to secure his retreat: nevertheless, the general should endeavour to make the most of his victory, and should never be content to win a battle by halves; at least it should be carried so far, as to make the enemy sensible of his loss, and of rendering him incapable of continuing openly in the field.

But if the army that attacks the lines should be unable to force them, after many repeated attacks, and if the general perceives his troops are discouraged, he should immediately retire. If the retreat is made over an open country, he should begin it by marching off the cannon, the infantry next, and the cavalry will form the rear-guard in two or three lines; the buffs and dragoons will be upon the flanks of the cavalry: if there are any defiles or woods to pass through, the general should leave some infantry at the entrance of them, to sustain and protect the cavalry, which will retreat by files. If the enemy is in full strength, the general should leave some field-pieces with the infantry that is posted at the entrance of the woods and defiles, which will certainly stop the enemy's impetuosity: if, on the contrary, the enemy pursues the army with only a few troops, it will be proper to charge him if he approaches too near. In this disposition an army may retreat easily, provided that order is observed, and the movements not made with too much precipitation.

SECT. VI. *Of the Attack of a Convoy.*

The same motive that ought to oblige a general to practise every resource of art, in order to conduct the effort of a convoy in safety, should also induce him to use the same expedients to carry off the enemy's subsistence, to oblige him to retire, if advanced into the country, into the neighbourhood of some one of his own towns, in order to find subsistence: to carry off the enemy's convoys, and deprive him of the means of subsisting, is, in reality, to overcome him without fighting. Vigilance, so necessary for all kinds of operations, becomes more particularly so for those which may decide the fate of a campaign. Whatever may be the nature of the convoys, a general should never neglect an opportunity of attacking them: if they consist of provision, the most numerous army in want of that becomes its own destruction; if of forage, the taking of that causes the ruin of the horses, and renders the cavalry useless: the ammunition necessary for carrying on war cannot be transported to the army, nor the artillery conducted to it. Without ammunition the wisest and bravest general cannot have any resource; and if destitute of money, the soldier is disheartened, and those very men whom pay renders heroes, are converted into so many deserters: the bravest man who, without fear, exposes himself, isensible to the greatest terrors of war, cannot support even the appearances of famine.

If the effort of a convoy marches in a mountainous country, the officer who commands it should have a body of infantry at his advanced guard, another at the

rear-guard, and a third in the centre; for it may happen that he may be attacked in flank, particularly if the enemy, discovering an opening, presents himself in the road that the convoy keeps; and there should be also troops in all parts to oppose any attack that may be made.

An advantageous method for attacking a convoy is, by forming three attacks, one real and two false. Those attacks are called *real* which the troops make with vigour and in full strength, and when their charging is provided for and determined; the *false* ones are when the general's intention is only to keep back the enemy, and prevent his sending assistance to the troops that are really attacked.

These attacks, true or false, are determined by the situation of the country, and in proportion to the degree of ease with which the convoy may be turned from the road it is in; that is, if the general should meet with an avenue near the advanced guard, which will draw the enemy some distance from his main body, and which also leads to that of the troops which attack, it is at that part the real attack should be made: if this avenue is found at the rear-guard, the two false attacks should be made at the advanced guard and at the centre, supposing there is an opportunity of attacking the centre. These false attacks ought to be sufficiently numerous in troops, to be able to employ the enemy, without running a hazard of being beaten, and to prevent his sending assistance to other parts.

If the troops designed to attack the convoy are sufficiently numerous, although divided into three bodies, to attack every part at the same time with equal vigour, the success will thereby become more certain. The effort of a convoy is often more numerous than the troops which attack it; but it being certainly weakened by the division it is obliged to make in order to guard the whole length of the convoy, the troops which attack have greatly the advantage, although inferior in number, because those which they attack cannot send assistance to the parts attacked, especially if attacked on all sides.

If the road is wide enough, and there is room for a waggon to turn, the general should rather choose to attack the advanced and rear guards than the centre, to prevent the enemy's saving any of the waggons belonging to the rear-guard, which will undoubtedly be the case, if only the advanced guard and centre are attacked. If the road is so narrow that the waggons cannot turn about in order to go back, the general should attack the advanced guard, and employ the centre and rear-guard as much as possible.

A convoy may also be attacked at the opening of a defile into a small plain; then it is again the advanced guard that the general should attack, who should also contrive to have the rear-guard attacked at the same time. The troops in the centre will be confused, and not know where to send assistance, because they will hear firing both in front and rear; nevertheless, the general should defer charging till part of the waggons are passed, and the troops of the centre are still on this side the defile. An attack, when unforeseen, brisk, and sustained, can never fail succeeding, particularly when the troops attacked are so divided as not to have it in their power to assist each other; and if the whole convoy is not taken, there is almost a certainty of taking

king

king a great part of it, or at least depriving the enemy of it, by setting it on fire, and by hamstringing the horses, if there is not time to carry them off.

The success of these attacks partly depends upon the choice of those places where the troops which are to fall upon the convoy are placed in ambuscade; the most secure are those which are least liable to the inspection of the enemy's parties. It is sufficient to have sentries upon the tops of the hills, so that they may see into the roads, and give notice when the convoy is near the place appointed for the attack: then the troops charged with the attack of the rear-guard, having nothing more to apprehend from being discovered by the enemy's parties, may draw near the entrances of the avenues.

If the ambuscade is discovered, the conduct which ought to be observed by the troops composing it depends entirely upon their force and that of the escort; nevertheless, even when they are weakest, the attack should be attempted, which, if unsuccessful, will at least have retarded the march of a convoy, for want of which the enemy may be greatly distressed. A general never risks much in attacking a convoy; the object of the officer commanding the escort being to conduct it in safety, and to avoid fighting: it is the same with the escort of a convoy, as with a chain of forage, the end of which is only to complete it; and consequently the troops charged with them will rather be attentive to execute the orders which have been given them, than to pursue the enemy, although beaten and drove back. The conducting of a convoy, and the dispositions which relate to foraging, are very different from those of a detachment only: foraging and convoys have a fixed destination, and a point where they are to terminate; whereas a detachment has no other view, than to seek the enemy and fight him, unless it is ordered to carry assistance, or to get possession of some post. Then the commanding officer should act in the same manner as if he was charged with the conduct of a convoy or a forage; that is, he should endeavour to execute his orders without fighting: but if the intention is only to seek the enemy, the troops in ambuscade, finding themselves too weak for him, should retire; but if they are superior, or even equal in number, they should attack him, and the vigour of their charge should determine the success of it.

In a woody country the situation of it should be considered, in order to regulate the manner of the attack: if the wood is thick, infantry only can act in it; if it is not thick, some hussars or dragoons may be added to it. If the road through which the convoy passes is large, the advanced and rear guards should be attacked; the troops in the centre will be easily kept employed by a few troops: if the road should be so narrow, that the waggons can neither turn back or double up, the head should be attacked, and the false attacks made at the rear-guard and the whole length of the convoy.

When a convoy marches through an open country, there should be many ambuscades formed: an enemy is less apprehensive in an open country, because, seeing all before him, his searches become the less exact, in proportion as the country is unfavourable for troops to form ambuscades; nevertheless, a general may always find some hollows, heights, or places of the same

nature, where troops may be concealed. As soon as the convoy shall be arrived at the place fixed on for the attack, the general should fall upon the advanced and rear guards, in order to take in the whole, and to induce, if possible, the troops in the centre to divide themselves, to run to their assistance; then the third ambuscade must show itself, and attack the centre, and endeavour to divide the convoy, before the command of the escort has had time either to park it or double it up. If the general succeeds in dividing the convoy, and if the troops in the centre of the escort are beaten and broke, he should detach some infantry, cavalry, and hussars, in pursuit of them: the remainder must be divided in two parts, in order to attack the troops lining the convoy; after which they must join those who attack the advanced and rear-guards. The troops, when re-united, ought to make this attack with vigour, and entirely determine the defeat of the escort, and consequently the taking of the convoy.

A convoy that is divided is half taken, as soon as the detachment of the centre is beaten; because the victorious troops can be divided, and part sent in pursuit of the body that is beaten, and the other part employed to reinforce those who still meet with resistance; whereas, if only one part is attacked, that which is not attacked can readily send assistance, especially in an open country, where there is nothing to prevent either cavalry or infantry from acting, and being a mutual assistance to each other.

A general who would attack a convoy never runs any hazard by dividing his troops, in order to divide those of the enemy: the more the troops of an escort are divided, with the greater ease will they be beaten. An officer who would attack, should know the strength of the escort, in order to regulate the number of his troops by the enemy's, and to be proportionably stronger. He who is attacked, being ignorant of his enemy's force, and being charged on all sides, is at a loss where to send assistance, and how to take care of every part: he who attacks by the knowledge he should have of the country, is enabled to post his troops after such a manner, as to employ all those belonging to the enemy, without weakening himself. The troops which attack have certainly great advantages, because, in dividing them, they are still stronger than the body attacked; and then they can choose the place most favourable for the attack: whatever may be the precautions taken by the officer commanding the escort, whatever may be his vigilance, it will be very difficult for him, considering these different attacks and the number of the enemy's troops, to dispose his own with sufficient quickness to place the convoy in security, especially if the attack is made with great quickness and vigour.

The attack and the defence should always be provided against, and the most certain means for succeeding should be taken beforehand. Upon this principle he who would attack a convoy ought to be informed of the day it is to set out, and the number of troops with which it is to be escorted. From the knowledge which he ought to have of the country, he will place his ambuscade out of the sight and searches of the enemy's advanced detachments; he will choose such places for the attack as are most favourable for him, and most disadvantageous for the enemy; and should the

convoy

convey have a bridge to pass, that will be the most favourable place for the attack.

On this occasion the commanding officer should divide his troops, which ought to attack, into three bodies: two must be placed in ambuscade on the opposite side of the bridge, and the third remain on its own side. As soon as the officer of the troops in ambuscade shall see the head of the convoy, he will permit the advanced guard, the body at the centre, and some waggons, to pass; then the two bodies in ambuscade on the opposite side of the bridge will show themselves, and charge the troops; one those of the advanced guard, and the other those of the centre: he will also permit some waggons to follow the troops of the centre, so that the passage of the bridge may be embarrassed; the third body, which is on its own side, ought to march in order to attack the rear-guard, which cannot have any communication with the advanced guard and the troops of the centre, the passage of the bridge being stopped up with the waggons with which it is covered; and because also the advanced and rear guards are attacked. It is to be presumed that these three attacks, made at the same time by superior force, will have the whole advantage of the action; and the more so as the troops of the escort being every where employed, cannot send assistance to any particular part. If the two bodies which attacked the advance guard and the centre should break them and put them to flight, there should be troops enough left in pursuit of them to finish their entire defeat, without any fear of being repulsed; the remainder ought to march to the bridge, and cause the waggons that are upon it to be ranged in order, and march to the rear-guard, in order to finish its defeat, if it still continues to make resistance.

It is necessary to observe, that some troops ought to be left at the head and along the convoy, in order to take care that the horses are not taken off from the waggons, and that none of the soldiers or drivers make use of that method to escape.

If the general has not troops sufficient to be divided into three bodies, the ambuscade on this side the river can no longer take place, but the advanced guard and the centre must be vigorously attacked. The general must observe not to attack till the troops of the centre shall have passed: this attack should always be executed by the infantry with the bayonets fixed, and without firing, and by the cavalry, hussars, and dragoons, sword in hand. The general should not then stay to make prisoners; but should put to death all those whom he finds armed. If the two first detachments are beaten, the general should march with the remainder to the rear-guard, which, not being strong enough to resist a body of troops much more numerous, will undoubtedly betake itself to a retreat. As it is the convoy, and not the troops of the escort, that is the principal object, the general should leave only some troops of hussars to pursue the rear-guard; he should make the waggons file off as fast as possible, and conduct them the nearest way to the camp or the neighbouring town.

If the action has happened at too great a distance from the army, and waggons cannot be conducted without running the hazard of being attacked, the traces must be cut, the horses carried away, and the

waggons set on fire. The hussars and the dragoons which have been left in pursuit of the advanced and rear guards and the centre, should not follow them more than half a league, and then ought to return, in order to form, together, the rear-guard of the convoy that is taken: to which some infantry should be added, especially if it is to pass through a woody country; if it is in a mountainous country, the pursuit of the enemy, as well as the rear-guard, on the return, ought to be entrusted to the infantry.

SECT. VI. *Of the Attack of green and dry Forages.*

NEXT to the convoys, the forages become most necessary for the subsistence of an army, as it is by them the cavalry is supported; and if a general can contrive to deprive the enemy of them, or to molest him in the making of them, his cavalry will soon be without resource, his infantry without baggage, and his artillery without the means of being conveyed. An army, however numerous, reduced to this extremity, is necessarily obliged to keep upon the defensive, however inferior in number or troops the army opposed to it may be, its movements will tend only to find subsistence, and all its designs will be by that means destroyed. A general who is so vigilant as to seize on such like opportunities, will fight more securely, and, instead of continuing upon the defensive, he will find himself in a capacity of acting offensively.

With regard to green forage, it is necessary the general should be informed of the time and place where it is to be made, and, if possible, of the number of troops which are to forage. In consequence of this knowledge, he will calculate the extent of ground they will take up, and also the number of troops necessary for forming the chain: from this judgment, and upon this examination, he must make a detachment sufficiently strong to attack the chain in many parts; and should also be sure, by the number of attacks made in different parts, of penetrating on one side or another.

A general should, on this occasion, make use of ambuscades; it is a very useful and also secure method of acting, when well performed. War, in the field, is almost entirely founded upon ambuscades; the great point consists in knowing how to place them advantageously: but it is unnecessary to enlarge upon this subject here, there having been a sufficient detail given of it in the second section of this part.

If the forage is made in an open country, the detachment destined to attack it, should be composed of infantry, cavalry, and hussars: the infantry should not appear, but ought to remain in ambuscade in some hollows, behind some hedges, and other favourable places; and it should be careful not to show its arms; because, by the glittering of the steel, they may be discovered: the cavalry should be divided into two bodies, three quarters of a league one from the other, taking care to be able to join in case of necessity. As for the hussars, they should be distributed about in many small detachments to the right and left, and in the centre of the two bodies of cavalry; upon one of the flanks, there should be a more numerous body of hussars placed in ambush, at a greater distance than the small detachments. Every one of those small troops should have a number of trumpets with them;

Offensive
Operations.

and when the chain is formed, and the foragers spread over the plain, a part of these detachments should leave the ambuscades, making a great noise, and attack those belonging to the enemy which are advanced: and these detachments will charge them with so much the more vigour, as they will be sustained by the large body of hussars in ambuscade behind them, and which should march to sustain them, and attract the attention of the officer commanding the effort. It may happen that this first attack, made on one side only, may induce the enemy to unfurnish the chain in some place, by which it will consequently be weakened; that is the time for the other detachments of hussars to advance, followed by one of the bodies of cavalry, in order to attack the part that has been unfurnished. If the enemy, more prudent, does not weaken the chain in any particular part, which is every where strong, but contents himself with making the reserve march to the assistance of the troops which have been attacked, the second attack ought always to take place; but in order to employ the enemy every where, the second body of cavalry should march and attack the centre. This attack ought to be made with great briskness sword in hand, whether the enterprise succeeds or not: if it succeeds, a great advantage may be drawn from the rout of the chain; and, by pursuing the troops of the chain with the cavalry and part of the hussars, the other part should fall upon the foragers, where they will without doubt find but little resistance: if the attack does not succeed, and that, by the good disposition of the troops of the chain, the detachment has not been able to force it, it should retire to the infantry that has remained behind in ambuscade; this infantry will facilitate the retreat of the cavalry and hussars. But suppose, that the enemy, too eager, is carried away by this first success, a great advantage may be derived from his imprudence, by attacking him resolutely. The whole strength, and each body being united, it is to be imagined and even hoped, that the advantage will turn on the side of those troops which were repulsed but a moment before; and the more so, as the general commanding the chain can have pursued only with his cavalry, his hussars, and dragoons, because his infantry will have remained in the posts which it occupied, either to guard them or to sustain the horse, supposing they should be repulsed.

If the forage is made in a mountainous country, the infantry must act alone, the cavalry being only necessary in case it can have any ground on which to act, and sustain the infantry in case it is repulsed; the infantry should attack the avenues and the heights, and possess itself, as much as possible, of those which have the greatest command, and make the attack in many places, as in an open country. These different attacks render the enemy undetermined with regard to his dispositions; he does not know where to send assistance: the uncertainty of the general becomes visible to every officer, and soon communicates itself to all the troops; from thence proceeds their confusion, and consequently their defeat.

When the enemy is beaten and driven off, the detachment should pursue him far enough to prevent his returning to finish the forage; taking care not to go too near his camp, from whence there may come assistance, because the alarm will have been undoubted.

ly carried there by the foragers who may have escaped.

The prisoners and horses that have been taken should be sent off first with an escort; the rest of the troops will retire immediately after by the shortest road. It is cruelty to abandon the wounded, whether friends or enemies; and as the detachment has undoubtedly found, within the circumference of the chain, some waggons with horses to them, they should be made use of to carry off the wounded, who should also be sent on before: if there are no waggons, the detachment must take them from the neighbouring towns.

The attack of a dry forage is conducted nearly in the same manner as that of a green one; but it is often necessary to employ a greater number of troops; because, as the forage is made in the villages, it is almost a certainty they will all be guarded by infantry sustained by cavalry; whereas the chain of green forage is formed with a much greater number of cavalry than infantry, unless it should be in a country where cavalry cannot act. It is difficult to force the villages where infantry is sustained by cavalry; whereas it is easier for cavalry to attack each other in a plain, where the affair is immediately determined; but it is not so soon decided when entrenched infantry is attacked by infantry: but whatever resistance a commander may find, he should always attempt to force it. As the principal object is to prevent the forage, it is obtained by attacking the chain briskly and in all parts; because it is certain that the general commanding the forage will cause the foragers to assemble; or else, seeing the chain attacked, without waiting for an order, they will of their own accord disperse, and fly toward the camp: but whether they assemble, whether they retire in order, or shift for themselves, the end is answered, and the forage is left unperformed. If by their flight the commander cannot hope to make any prisoners, he must keep the troops of the chain at bay such a length of time, as to make it impossible to continue the forage for that day: he should even, if possible, endeavour to force them to retire; which if they do, he should pursue them long enough to be certain of their retreat, and then collect all the waggons from the neighbouring villages, cause them to be loaded with the forage intended for the enemy's army, and conducted to the camp: if they do not retire, the commander must remain in sight of them during the night, and send to the camp to demand a reinforcement of troops, in order to oblige the enemy to retire. For the same reason that a forage should not be abandoned till the last extremity, the troops that would prevent the enemy from making it, should be absolutely bent upon it, at the same time without exposing themselves to the danger of being beat by any assistance that may come from the camp to the troops belonging to the chain.

SECT. XI. *Of the Passage of Rivers.*

THE subject of this chapter is perhaps the most interesting of all hitherto treated of. This subject, which has never been thoroughly understood by the ancients, and upon which the greatest part of modern authors have but lightly touched, hath been placed in a new light by the chevalier Folard, in his commentaries upon Polybius.

Before an army attempts the passage of a river, it should

Offensive
Operations.

should be furnished with every thing necessary for it. Rivers are passed by swimming, fording, or upon bridges.

It is only small bodies that can pass a river by swimming; yet it will be very difficult to pass a river in this manner, particularly if the enemy makes the least effort of opposition. Antiquity furnished but few examples where whole armies have passed rivers by swimming. This trial was reserved for the French, encouraged by the example of their king, when they crossed the Rhine at Tolhuiz. It is an action, says M. de Feuquieres, the success of which was owing to its rashness, and which should never be cited as an example worthy imitation.

When a ford is discovered, it should be founded in every part, the goodness of the bottom examined, and whether the opposite bank is of difficult or easy access.

There are fords which become impracticable as soon as some troops have passed it, because the bottom has not been sufficiently firm.

If there is reason to apprehend that the enemy has armed the bottom with pointed iron, with stones chained together, or any other kind of thing, some soldiers should be sent with rakes to clear away every thing that may retard the passage; they ought also to take pick-axes and shovels with them, and indeed every instrument proper for removing of earth, because if the bank opposite to the ford is too steep, they will slope it properly.

If the river is not fordable, bridges made with boats or pontoons must be made use of; and if there is neither, then rafts. The reader may see what M. de Folard says upon this subject.

When a river is not sufficiently large to oblige an army to make use of boats or pontoons for the building of bridges, they are made upon piles, or upon wooden horses; then they are either fixed or flying. If they are supported upon piles, they are fixed; if upon wooden horses, they are flying. The method of constructing bridges with beams, or thick planks strongly fastened to each other, has been given in a former section; if the river is so wide that the beams or planks cannot reach from one side to the other, piles driven into the gravel must be made use of, that they may serve as props to the ends of the beams, in order to be able to establish the bridge; if the army is furnished with boats or pontoons, they had better be made use of, because the bridge will be the sooner completed.

The head of the bridge is secured by entrenchments of earth, that is, by sinking a ditch, and raising a parapet formed of the earth taken out of the ditch. These entrenchments are proportionably large, according to the use to be made of them, or the advantage intended to be derived from them. Sometimes an horn-work is erected, with an half-moon before it, the whole well fraised: a covered way palliaded is also sometimes added; but it is generally thought sufficient to cover the head of the bridge with an half-moon only; but that depends upon the importance of the post. Intrenchments are again made with waggons, where Turkish wells are made in the front; that is, deep holes, placed chequer-wise, at certain distances.

The passage of a river upon rafts is less dangerous than upon boats; but a very rapid river cannot be passed in this manner, because the rafts are secured only by ropes, which are liable to break: besides, this man-

ner of passing is very tedious, unless there is a very great quantity of rafts; and during the time they take up in constructing, three bridges may be built: this expedient should never be used except when there are no boats, and it would take up too much time to send for them. Rafts are joists of deal fastened together. In the chevalier de Folard, the reader may see those which he has invented: his contrivance for making the cavalry swim over is more ingenious than practicable.

The ancients had still many other methods for passing navigable rivers; they passed them, according to Vegetius, by means of wooden horses, which they sunk in the water; or else made use of empty tubs, which they tied together in a hurry, and floored; but, adds he, nothing was found more commodious than small boats, made of a single tree, very light by the quality of the wood, and which followed the army upon waggons.

Before a general engages in an enterprise so considerable as passing a river in presence of the enemy, he should, according to the chevalier de Folard, consider opportunity; the condition of the enemy's forces; by what circumstances the attack and the defence may be prevented or facilitated, and compare them together: he should examine the nature and the course of the river; remark the places where the fords are, the size and depth of them, their distances from one another, the nature of the bottom, whether it is firm or boggy; if there are marshes either on one side or the other, whether these marshes are practicable; whether the passage will become difficult in proportion to the numbers which pass; whether the banks are steep, and at what part they are most so; whether the ground on the opposite side is more favourable for infantry than cavalry; the heights on this side to place cannon on them; those which are on the other, where they may be carried; the nature of the river, whether it is apt to swell on a sudden by the rains, or the melting of the snow.

Whenever a general attempts the passage of a river in strength, as the whole advantage will be on the side of the opposing party, he should suppose the enemy vigilant, resolute, capable of profiting from circumstances, steady in his resolutions, and ready to try all possible means of opposing the passage.

A general should be particularly acquainted with the nature of the banks of the river, as well those of the opposite side as of that where he is, in order to be strong in every part, and that all the attacks may be equally made, and that with every advantage the ground will allow. In short, it is very essential for a general to be acquainted, not only with every thing relative to the rivers he has to pass, but also with all concerning rivers in general.

These principles established, this section will be divided into four articles; in the first, an army shall be supposed to meet a river in its march, which it is obliged to pass.

In the second article, the defence necessary to be made for opposing the enemy, and preventing his passage, shall be treated of.

Thirdly, shall be particularized the means which a general should employ in order to facilitate the passage, notwithstanding the enemy's opposition.

Fourthly, the secret method of retreating shall be demonstrated by facts.

ART. I. It is easy for an army to effect the passage of a river when the enemy is at too great a distance to oppose it. A general may choose his own time and place, and make what disposition he thinks proper: he may either pass it upon bridges, rafts, or at a ford; if he finds a ford, he may let the cavalry pass there, provided the bottom is good; it is much better to throw over a bridge for the infantry, than to expose them to the wet, and unnecessary fatigue.

"Infantry," according to M. de Montécuculi, "is the basis and the support of an army, whether for battles or sieges; and it is with that the Romans and the Swifs have performed such surprising exploits." A general should therefore be very careful of it, and not expose it to the danger of diseases, by making it ford over rivers, when it is as easy to cause it to pass over upon bridges. The artillery and baggage should likewise pass over upon bridges: thus, instead of causing two or three bridges to be made, one or two only will be sufficient, according to the number of troops composing the army, upon which the infantry, artillery, and baggage will pass, while the cavalry ford it over; if there is no ford, the general should order many bridges to be built, in order to expedite the passage.

The method of turning the course of rivers, laid down by Santa-Cruz, by choosing a spot lower than its channel, making of trenches, and by forcing it to take a new course, by the great quantity of stones which are thrown into the channel, is an enterprise to be executed only upon small streams, or by armies such as those of Xerxes, whose thirst, according to Juvenal, could dry up a river in a day.

As to the manner by which a general may open himself a passage across the waves, it would be easier, in case of a deficiency of boats, and if time and the enemy's distance would allow of it, to make a causeway by the means of piles and stones, and by raising up the ground. The only inconvenience to be apprehended, is, that the waves coming in front, and their body being augmented by this impediment, the force of the water will probably break the bank; therefore, in order to render it more substantial, it should be made with an angle in the centre, and each side of it should be sloped like a glacis. But these operations require a length of time too considerable, and labours which would be too tedious and fatiguing.

The ropes which are sometimes thrown across rivers, and which serve as a support for the infantry, when the ford becomes too deep, may prove of some use; but it is to be feared, that the soldiers, by hanging to it, will only embarrass each other, and that those in the front will be a hindrance to those who follow.

Santa-Cruz proposes that some squadrons of horse should be placed at the head of the fords, who should keep themselves firm and close together, in order to break the force of the current, while the infantry shall pass lower down, and that they shall open from time to time, in order to let the waters they have retained run out.

He would also have some squadrons at a greater distance, in order that any soldiers which may have been carried away may be stopped there; but this contrivance can be of no use against the depth of a river, it can only be serviceable in stopping the rapidity of it: Vegetius also never practised this method but on an occasion of this sort.

But after whatever manner the fording of a river is attempted, the troops should form as large a front as possible, as they will by that means be better able to resist the violence of the current, and will find themselves in order of battle after the passage is effected.

As to the passage of a river upon rafts, the infantry who pass first can take the end of a rope with them, the other end of which will be tied to the extremity of the raft; and as soon as they shall be landed, they will draw these rafts to shore. As soon as the cavalry on them shall have debarked, those on the other side will draw the raft back, with another rope that shall be fastened to it, and by degrees the whole cavalry will pass: in order to shorten this passage, many rafts should be made use of.

It is again more secure, when practicable, to cause the infantry to pass, mounted behind the cavalry: but then it is also dangerous; because if the enemy presents himself on the other side, both trooper and foot soldier will be confused, and it will be with great difficulty that either the one or the other will be capable of defending themselves, as they cannot dismount readily enough without embarrassment. The least impediment on this occasion throws the troops into disorder, and exposes them to the danger of being drowned, or to retire disorderly by swimming, which cannot be done without considerable loss: this method cannot be put in practice, but when there is a certainty of the enemy's being at a distance.

It sometimes happens that an army crosses a river, which swells all on a sudden by the melting of the snow. In which case a general should be cautious, as Santa-Cruz remarks, not to undertake the passage, but in proportion as he shall be certain, that the whole army, artillery, ammunition, provisions and baggage, shall have passed before the flood is at its height. In the same place he points out the precautions which ought to be taken to prevent confusion among the troops during their passage.

ART. II. It would be impossible to run through every precaution that can be taken to dispute the passage of a river; we shall therefore confine ourselves to the principal ones, by a succinct relation of the different systems of the authors who have treated on that subject.

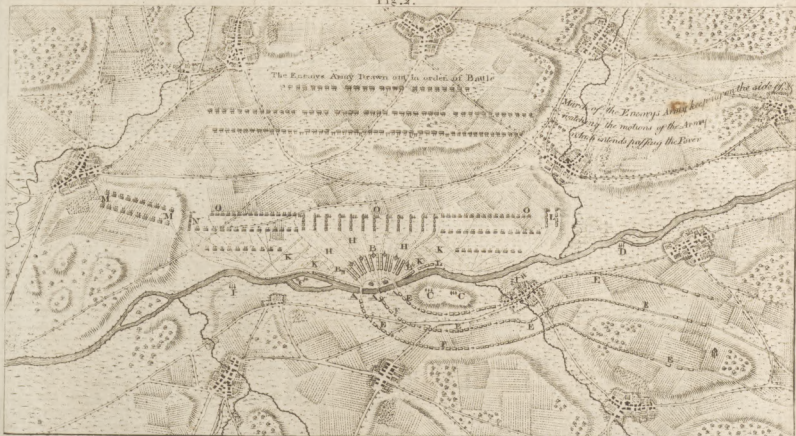

In the passage of rivers, the whole advantage is on the side of the army on the defensive. Nevertheless, the chevalier de Folard observes, that it is very seldom that a general attempting the passage of a river fails in his undertaking; for which he assigns two reasons: 1. Because the general who would pass, by false attacks, obliges the general on the defensive to divide his army into so many different bodies, that he becomes weakened in every part. 2. Because he cannot have any information of what is doing in the enemy's army, and is ignorant of all the enemy's designs, till such time as they are put into execution. There is still a third, which results from the first, and which seems very plausible: It is, says M. de Fenquieres, impossible to cover the banks of a river, when the ground to be protected is of a great extent, because the assailant who seems to make his effort in many parts, at length determines upon that where he finds the least resistance; but if he who is on the defensive knows the river, and is as well acquainted with the fords as he who attacks, why is he

A. Belloups.

not as well able to oppose the enemy, stratagem by stratagem? According to M. Feuquieres, the most certain method on this occasion, is to keep together, within a reasonable distance of those places where the enemy can attempt the passage, and to have persons whose vigilance may be depended on, upon the bank of the river, so as to receive information in such a manner as to have time sufficient to fall upon the enemy, with the whole army, either before he shall have entirely passed, or before he shall have been able to form himself in order of battle.

The first precaution to be taken, according to the chevalier de Folard, is, to draw off all the boats which are upon the river; to observe whether any other river has a communication with it; to examine the course, the windings, and the most accessible parts of it; to raise good redoubts near the banks; to ascertain the bottom by means of sacks and baskets filled with stones, large trees with their branches, and by stopping them with stakes.

To this precaution may be also added another, which, executed with exactness, may produce great effects; that is, to throw whole trees with their branches into the river, not so heavy as to sink to the bottom, but whose size and quantity shall be so considerable as not to be easily stopped; their branches should also be interwoven, and formed like a chain from one bank to the other; they should be held fast, till the enemy's army is engaged in the fords or upon the bridges, at which time they should be let into the current, the quickness of which will increase the force of this kind of moving bank, which will overturn every thing it meets with, soldiers, baggage, horses, bridges, and boats: in short, nothing will be capable of withstanding it if there is any degree of rapidity in the torrent. This method is pointed out in M. de Puysegur as levelled against bridges only. To avoid also giving any suspicion to the enemy, this chain of trees can be placed upon the bank of the river, of which some engineer must have been careful to take the dimensions beforehand; and when it shall be nearly the same size of the river, and the enemy is passing, it must be held at one end, whilst it is shoved off by the other: the whole of it will be taken by the current, which, without any other assistance will direct it against the enemy.

In regard to the troops designed for the defence, the best method, according to M. Folard, is to form small camps of 2000 or 3000 men, a league distant one from another, with guards and signals from one to another; to have canoes, in order that the river may be crossed silently in the night by soldiers, who will endeavour to make some prisoners, and who will also listen in order to discover whether the enemy is preparing to march. A general should particularly endeavour to possess himself of the islands, if any, under cover of which the enemy may attempt the passage; and if the general can be certain that the enemy's intention is to throw over a bridge where they are, in order to set out from thence, to save so much of the way, the general will by this means assure himself of the place where the enemy will attempt the passage, and which circumstance will be almost sufficient to prevent him.

But in case the general can get possession of these

islands, and plant cannon upon them, the passage in that part would then become impracticable for the enemy; for besides the fire of the cannon driving him from the shore opposite the island, it would also greatly annoy him on the right and left, to a considerable distance.

But, in order for the better explaining of the manner in which a river should be defended, let two armies be supposed, one of which, consisting of 40,000 men, defends the passage against another of 60,000. This last is divided into three bodies; that of the centre consists of 40,000 men, and the two others of 10,000 each: the centre-body is encamped nearly opposite to the place where the passage is intended to be effected, of the two bodies which are upon the flanks of the centre, one will serve to keep the enemy in suspense, with relation to the true place where the passage is designed. They ought to be continually moving, sometimes at a distance from the main body of the army, and pretend to throw bridges higher up, or lower down, in order to induce the enemy to divide and separate the different bodies of his army in such a manner, that they can no longer be of assistance to each other, or be in a condition of opposing a superior body of troops that may attempt the passage.

The army defending the passage is divided into many bodies; three of 10,000 men each, at a league distance from one another, and two others of 5000 men each, composed of the light troops, both horse and foot, and dragoons, encamped at half a league upon the two flanks of the army. The communications should be preserved between each separate body, and constant patrols kept upon the side of the river, which ought continually to cross each other; and detachments of hussars upon the right and the left, both up and down the river: the general is also supposed to have planted batteries of cannon, in different parts upon the shore; and to be possessed of two islands which he has fortified, and in which he has also placed troops and cannon: in short, he is supposed to have taken every advantage of ground, for rendering the passage difficult to the enemy, and to oppose troops to him in every part where he may attempt it. It is impossible to be certain, that the enemy, notwithstanding all these obstacles, will not effect his passage; the means of hindering him, and rendering the passage very difficult and bloody to him, can only be laid down. By the most prudent precautions, the probability, but not the certainty, of success may be determined. See Plate CCXCIII. fig. 1.

If, notwithstanding all these obstacles, the enemy attempts the passage, he should be attacked as he debarks: it is that reason therefore which makes it essential not to divide the troops into too small bodies, which, too weak to resist a superior number, will be easily routed. In attacking the enemy's troops, there is no danger to be feared from their cannon, which they cannot make use of without annoying their own troops; whereas the cannon planted upon the side of the river, to defend the passage, can always fire upon the troops which follow, in order to sustain those who attempt the passage: there should also be infantry placed near these batteries, to defend them, and to flank such of the enemy as have already passed.

There yet remains many stratagems to be praised

Offensive
Operations.

on these occasions : a general may make use of those mentioned in the section which treats of ambuscades ; and they should be particularly directed against those places which are supposed to be most favourable for the enemy. The history of prince Eugene, whom the chevalier Folard styles a great traverser of rivers, furnishes many examples.

The general should be particularly attentive in disturbing the enemy when constructing his bridges ; which appears the more practicable, as the bridge is never properly established, if not guarded at each end : besides, by the assistance of artillery, the enemy may be easily prevented from going on with his work. M. Feuquieres, in the passage already cited, relates examples where the enemy hath not been able to prevent the bridges being built under their very noses ; but besides the rarity of these examples, the precautions he used are a very convincing proof of the difficulty attending such undertakings.

A prudent general, and one who is himself acquainted with the river, of which the enemy would attempt the passage, is guided by its depth, by the difficulty of gaining its banks, and in proportion to its rapidity : he often pretends to be inactive, permits the enemy to throw his bridges over it, and waits till he is in the middle of his passage ; at which time he makes a furious fire upon him, spreads disorder amongst his troops, and overthrows his ranks ; and the enemy, besides losing a great number of men, also fails in the success of his enterprise.

A general may turn a town on the other side of the river, either of his own or one in alliance with him, to great advantage : in this situation he should cause a body of troops to form a camp on the other side, reaching from the river to the town, in order to be a check upon the enemy, who will always be apprehensive of being taken in flank by this body if he attempts the passage. The rest of the army will be encamped on the side opposite to it, divided into many bodies, to guard a larger extent of country, that the army may be disposed in such a manner as to guard every part of the river.

In 1744, M. de Seckendorff took this position near Philipbourg, an imperial city, and garrisoned by the emperor's troops, then in alliance with France : if he had remained there, if he had repassed the Rhine, and joined the right of the army commanded by the marshal de Coigny, prince Charles would never dared to have attempted the passage, at least at the place where he effected it.

ART. III. As to the distribution of troops, for the passage of a river, a general should always, according to the chevalier Folard, regulate the order of his march, and the distribution of the columns of infantry and cavalry, according to the probability of coming to action. His dispositions, as well those relative to the passage, as the order to be observed upon coming to shore, deserve perusal. His reflections upon the passage of the Granicus are very just, and the reader is referred to them, as they would be too long to be related here.

When a general has discovered two or more fords upon a river, it is sometimes proper to attempt the passage at each of these fords, or at least to make the enemy imagine so, that, by having them all guarded,

Offensive
Operations.

he may weaken himself. Among the reflections of the same author upon this subject, will be found the stratagem made use of by Xenophon upon a like occasion. A general can also make as many false attempts as there are fords ; not at the places where the fords are, that would be the means of discovering them to the enemy ; but either a little above or below them, in order to keep the enemy's troops divided ; because, without that, an army not being able to pass all at the same time, would run the danger of being beaten, by degrees, during the passage.

A general who attempts a passage in presence of an enemy, should be very certain of his troops ; he ought to place the most intrepid in the front, in order to encourage those who follow them : on those occasions every thing is to be apprehended from ill-disciplined troops, because that, as soon as they are engaged in the river or upon the bridges, having no longer any place of refuge to fly to, they will be discouraged, and spread the panic throughout the whole army.

The emperor Leo relates, that his father, at the passage of a river, kept himself in the middle of the waves ; that he gave assistance to some, reached out his hand to others, and that he rescued many from the danger of drowning : it is thus a general ought to animate his troops. If, by his rank, he is exempted from exposing himself to the greatest dangers, he at least ought to encourage his troops, as much as he can, by his discourse and his example ; he should even share the most painful labours with them, and alleviate them as much as possible.

If the army passes upon two bridges, it is impossible to take too much care for their security : history is filled with fatal examples of bridges falling under the weight of troops. One of the greatest dangers ever experienced by Charles XII. was when, having caused a bridge to be thrown across the Vitula, the wood which had been made use of being too weak, and the timber-work ill secured, the bridge broke down whilst the king was passing. Charles, the prince of Wirtemberg, and many others, fell into the water : the king, having caught hold of a piece of the timber that was floating, was carried away by the current. The troops which had already passed found themselves at the enemy's mercy, who might have destroyed them ; but they did nothing, says the historian Nordberg, because of the heights of which the Swedes were in possession, and from whence they kept a fire upon the Saxons. Was it not rather an instance of the good fortune which usually attended that intrepid prince ?

It is probable, when a river is passed upon bridges in presence of the enemy, that they have been built before his arrival, and consequently there has been time to entrench them at each end, but particularly on that side next the enemy. These entrenchments should be made in such a manner, as to prevent the bridges from being flanked by the enemy's cannon ; therefore, instead of the entrenchments usual at the heads of the bridge, such as a horn-work, a crown-work, or a half-moon, the general should cause redoubts to be thrown up, the farthest of which should be 400 yards distance, and opposite to the bridge ; and the others should be thrown up nearer to the banks of the river, forming a semicircle ; in order for
their

their better defence, the general should follow the same dispositions which have been laid down in the preceding part. If there are many bridges, they should be constructed as near each other as possible, that the same redoubts may equally serve to cover them: the reason of these redoubts being placed at a distance from the bridges is, because that, as the troops pass, they will have room to form and sustain those occupying the redoubts. These redoubts undoubtedly require a greater degree of labour than is requisite for the construction of a half-moon, or even a crown-work; but it seems impossible to pass a river upon bridges in presence of an enemy, however strongly they may be entrenched, if there is not space enough left between the entrenchments and the bridges, to contain a number of troops sufficient to oppose the enemy, and to give time for the remainder of the army to pass. Labour should never be considered, when an enterprise is successful; a general, therefore, should never spare any pains for the attainment of his ends, but should take every precaution necessary for success, without troubling himself about the time and the labour it will cost: the glory of having forced the enemy to leave the passage open to him, makes sufficient amends for the trouble he has given himself in order to attain it.

A general who would hinder his enemy from passing a river, should be beforehand with him in all his designs, and be himself in a condition of attempting it. It is necessary that a particular account should be given of the methods of passing a river, by attacking the enemy, and facilitating the passage of the troops, against the enemy's efforts to the contrary. Mr Folard has laid down many different methods, which may be seen in his works.

Suppose an army of 60,000 men would pass a river, guarded by an army of 40,000. Let it also be supposed, that the army intending to pass has got the start of the enemy, either because he was not yet arrived, or because he has been amused with marches and counter-marches; that the general has also had time to construct three bridges, and to entrench them in the manner above-mentioned: he must begin the passage by causing these redoubts to be occupied by a battalion or half a battalion, according to their size; and he must plant cannon between those redoubts, with infantry to guard them. These dispositions being made, the army must march in three columns; the centre column must be entirely infantry, and the other two composed of infantry and cavalry. As the infantry passes the bridges, it must divide, and form columns, consisting of four battalions each, which must pass between the redoubts, having cannon upon their flanks: the cavalry must pass to the right and the left through the interval of the two redoubts nearest the river, and form in order of battle upon the flanks of the columns; the right wing with its right towards the river, and the left with its left. When all these columns shall be formed, and ready to march towards the enemy, the right and left of the two lines of cavalry must sustain it; and the right of those of the right, as well as the left of those of the left, will march to put themselves in a line in presence of the enemy: in this position the army must march towards the enemy and attack him, if he is so rash as to hazard an action; and if he should

retire before the army is entirely passed, the passage will be the more easily effected. See Plate CCXCIII. fig. 2.

From this disposition it appears, that the army which attempts the passage is almost certain of succeeding; it is sheltered behind the redoubts during the passage of the bridges; it has ground to form itself upon, and to show itself in full strength. If the enemy would attack the redoubts, he cannot so quickly carry them, but that assistance may be sent to them: besides, the cannon planted between each redoubt will prevent the enemy approaching it; or if he should, it will not be without losing a great number of men, a loss which will dishearten the soldiers, abate their eagerness, and give time for a part of the infantry to pass, to form itself in many columns, and attack with vivacity.

But it is seldom a general has time to build the bridges and entrench them after this manner, when the enemy is on the opposite side with an intention of disputing the passage: so circumstanced, he must endeavour to find some fords, and, under shelter of one or more islands, construct a number of rafts behind them; he must endeavour to keep the enemy at a distance from those places, by marches and counter-marches; and when that is done, he must cause the cavalry to ford over with grenadiers and labourers behind them; these labourers must throw up entrenchments as fast as they can, whilst fresh infantry is caused to pass over upon rafts. Provided these entrenchments can stop the enemy for some time, and contain infantry enough to resist him, the remainder of the army will be very soon passed: the cavalry will at the same time pass at the fords which have been discovered, in order to cover the flanks of the infantry; when it will spread over the plain, being itself protected by the infantry, as it leaves the entrenchments in columns.

The passage of a river cannot be safely attempted, if the general does not provide for a defence, and take infinite precautions to protect the army in its passage.

All that authors have said upon this subject, arises from this principle of Vegetius, which they seem to have commented upon, and to which they have applied different examples. "As the enemy (says he) are accustomed to form ambuscades, or to attack openly at the passage of rivers, the general should post himself beforehand of a good post on the opposite side, and entrench himself even on that on which he already is, to hinder the enemy from attacking his troops, separated by the channel of the river; and still, in order for greater security, the general should cause the two posts to be entrenched and well palisaded, that in case of an attack, he may be able to sustain the efforts of the enemy without great loss."

It may not be improper, in this place, to relate a disposition of M. de Valere's, formed upon this principle.

He says, "After the cannon are planted, a parapet should be raised upon the banks of the river, 200 yards in length or thereabouts, behind which some infantry should be immediately landed from the centre of the parapet, and some soldiers with labourers sent over, who must immediately erect a small half-moon: as soon as that is done, more soldiers should be sent in order to defend it in case it should be attacked; more labour-

Offensive
Operations.

ers should also be sent to erect another half-moon, both upon the right and the left.

"If the labourers are not annoyed by the enemy, they should at the same time erect a horn-work, whose wings should be flanked by the first parapet, and the cannon planted in it: if the river is so large, that the wing of the horn-work cannot be defended by musquetry, it must be defended from the half-moon, made from thence to the water."

In the mean time, the general should cause the bridge to be continually worked at; and, as soon as it is finished, make the troops pass over it, if the enemy is not in sight; but if he is, the horn-work must be completed, to prevent the enemy from falling upon the troops as they pass. The horn-work being made as strong as is judged necessary, as much infantry as it will hold should be lodged in it, with some field-pieces; and as the cannon upon the rising will keep the enemy at a distance, the general may order the cavalry to pass: but still all this cannot be effected but before an army very inferior. If the enemy's army is of superior force, the safest method is to try a passage at some farther distance, still keeping the army in sight as long as possible, and concealing from the enemy that any troops have been detached.

It is impossible to foresee every stratagem that may be employed, as they depend upon many circumstances; but it is always right to send, if possible, some trusty spy to discover the enemy's position on the other side of the river, what obstacles he can place in the passage, what methods are to be used to avoid them, and what parts of the bank are most accessible or best guarded.

A general should make many false attempts, particularly at those parts where he least intends passing; they should be made as secretly as possible; and also, in order to deceive the enemy, the general may throw over two or three bridges at hazard, in sight of the enemy, at those very places where he has resolved not to pass: the enemy's whole attention will be directed to that side; and a constant fire should be made on him from the other side, so that he may not be mistrustful of the stratagem. There is no doubt of these bridges being taken, which is of no consequence, provided the enemy is amused, and the general has time to throw over another bridge at a distance from that place, by which he can pass.

Cæsar's method may also be practised, which he made use of in order to pass the Segre, whose opposite shore was guarded by Afranius. (*De Bell. Civ. l. i.*)

By uniting these two methods, a general can, whilst he amuses the enemy by a feigned passage, or by the bridges which he has thrown over at hazard, make use of the portable boats, and effect a passage at those places which the enemy have abandoned in order to oppose himself to the bridges.

Whenever two armies are on either side of a river, a general may pretend to have abandoned all design of passing it, and seem to proceed on his march as if he would attempt a passage elsewhere.

If the enemy should follow the army on the opposite shore, the general may leave a brigade of infantry, pontoons, and cannon, in a wood, or behind a hill, to wait till the enemy abandons his post, in order to follow the army that is marching lower down; then those who have remained behind will throw a bridge over the

Offensive
Operations.

river, which they will pass, and entrench the head of the bridge. That being done, the general will detach some brigades of infantry and artillery to reinforce the troops which have already passed; so that being joined, they will be sufficiently strong to give the rest of the army time to arrive and effect the passage.

It would be impossible to recapitulate every stratagem which a general may practise: in the histories of prince Eugene and Charles XII. the reader may see the different methods which they made use of; it will be sufficient here to relate the rules laid down by Montécuculli, with some modern examples, by which they seem to be corroborated.

1. The general must plant artillery upon the bank opposite to the post he intends taking; which will be attended with great advantage, if the river forms a re-entering angle, and if there is any ford near it.

2. In proportion as the construction of the bridge advances, he should post some infantry upon it, in order to keep a fire upon the opposite shore.

3. When the bridge is completed, he must cause a body of infantry, some cavalry, some field-pieces, and some pioneers to pass it, in order to fortify the head of the bridge on the other side.

4. The general must take great care that the enemy has not poited armed barks, or other machines, to break down the bridge when half the army shall be passed.

5. If the general would preserve the bridge, he must fortify it at both ends, and place sufficient guards in it.

In 1743, prince Charles intending to pass the Rhine, kept a continual fire upon all the French posts from 11 o'clock at night till three in the morning, in order to conceal his real design with regard to the passage.

Marshal de Coigny assembled his army in three large bodies; and lay all night upon his arms, the only prudent step he could take on that occasion.

By this disposition he found himself in a condition of transporting himself opposite to the isle of Raigance, of which the enemy was in possession; and it is well known, that they ended the campaign there, without being able to penetrate into Alsace.

The number of columns ought to be regulated by the breadth of the ford, or by the number of bridges that are established.

The third of June 1747, at day-break, the army commanded by M. de Belleisle passed the Var in five columns.

This passage was effected without any resistance on the part of the enemy, and M. Belleisle had 15 men drowned, although there was a chain formed of peasants, acquainted with the fords, to direct the march of the columns, and to assist the soldiers who were carried away by the rapidity of the current.

ART. IV. All passages of this nature, whether in a march, whether in defence, or for an attack, may be foreseen. A general may, at a distance, make all the preparations necessary for these operations; he may anticipate or foresee the dispositions of the enemy: in regard to a retreat it is otherwise; for although it may have been provided for, a general cannot be certain whether it can be effected after the manner he hath intended; besides, he must, in a retreat, unite all the different dispositions already mentioned: the least negligence becomes irreparable, and gives the enemy a very great

great advantage. A moment lost, a movement discovered, may also be the cause of a rout, and render the retreat impossible, or at least very bloody; therefore if a general, in these circumstances, has not a perfect knowledge of the river he has to pass, if he has not been careful to preserve the bridges, or to keep the materials and instruments proper for the throwing over of new ones, he will be unable to pass in sight of the enemy. Xenophon's retreat with the 10,000 Greeks, furnishes examples of the passages of rivers, which a general should always have present to his view. What prudence, what activity in founding the fords himself, whenever he met with any stream or river to be crossed! What orders to prevent confusion among his troops, and what stratagems to avoid being repulsed!

If a general is certain of returning by the same place, at which he has formerly passed, the best way would be, as Vegetius says, to have the bridges guarded, and to erect a fort with large ditches at the head of each, for their security, and to place troops in it to guard the bridges and the passage, as long as shall be thought necessary.

Thus circumstanced, a general should entrench the heads of the bridges in the manner directed in Art. 3. and that the troops may pass the bridges without confusion, according as one brigade of infantry shall enter the circle formed by the redoubts, another shall pass the bridge, and that which enters shall take possession of the posts which that which passes occupied; he must be careful to establish batteries of cannon to the right and the left, on the other side of the river, to flank the redoubts, and defend the approach to them; so that when the whole army shall have passed, the troops who occupy the redoubts may retire with ease. The cavalry will pass the bridges without stopping behind the redoubts.

In a retreat of this kind, the infantry should march in column, and the cavalry in order of battle, upon the flanks of the infantry. Before the march is begun, some troops must be sent to occupy the redoubts; as soon as they shall be in possession of them, the army will put itself in march, and proceed towards them. The cavalry of the right must pass over the bridge nearest to it, and that of the left will do the same. The columns of infantry must enter by the spaces which are between each redoubt; the grenadiers and the piquets must remain, in order to sustain the troops occupying the redoubts: some pieces of cannon should also be left to fire upon the enemy in case he should approach too near; the columns must pass over the three bridges; the grenadiers and the piquets must also draw near the head of the bridges at night-fall; the troops occupying the redoubts must quit them silently, and pass the bridges; they must be followed by the cannon that has been left during the day; the grenadiers must pass last of all; after they are passed, the bridges must be broke down. This may be easily executed, provided order and silence are preserved; but if the enemy entertains the least suspicion of the redoubts being abandoned, he will come in full strength to attack the troops still remaining on that side. These troops, too weak to resist a superior number, cannot avoid being beaten, slaughtered, or drowned, the cannon taken, and the bridges burnt.

For greater security, the grenadiers and the piquets

Vol. X.

may be furnished with chevaux de frise, which will make an entrenchment, till the troops which occupied the redoubts are retired. A retreat never merits the epithet of *fine*, except it is performed with order, and with the loss of as few brave men as possible, to save the rest of the army.

In every enterprise formed by a general in difficult places, he must, according to M. de la Valiere, provide for his retreat. In retreats of all kinds, adds the duke of Rohan, a general cannot be too attentive to render it safe, and to avoid disorder: when it is the effect of his own choice, it ought to be made so early, and so expeditiously, that he may not be under a necessity of fighting.

During the passage of a river, or even after a general has passed it, if he should be repulsed, the retreat becomes very difficult, and cannot be performed without great loss; it is for that reason that many generals, who have been mistrustful of the firmness of their troops, have burnt their ships in the port, in order to animate them to victory, from considering the impossibility of retreating.

The passages of the rivers now going to be mentioned, will serve both for examples and rules. The particulars which will be entered into, will leave nothing to be wished for by those who are desirous of instruction only.

In the campaign of 1742, the disposition of M. Saxe for passing the Danube, owed its whole success to secrecy, to the general's address in profiting by circumstances, and particularly to a very thick fog.

The two armies were encamped two leagues distant from each other, and the light troops skirmished together the whole day.

At seven o'clock at night, count Saxe sent for the general officers, furnished them with instructions, and caused the guards to be doubled.

At nine o'clock, the baggage filed off over two bridges; one of rafts and another of piles: after which the infantry passed, and the grenadiers, who formed the rear-guard, cut down and burnt the two bridges. The enemy advanced in order to charge his rear-guard; but 18 pieces of cannon that had been planted beforehand, very soon silenced the fire of their musketry, and he lost not a single man.

At day-break the army formed in order of battle, upon two lines, in order to give time for the Imperialists to retire from Pladling; and as soon as they had joined, the army put itself in march in four columns.

It is particularly necessary, either in passages or retreats, to be acquainted with the nature of places, and if they are fit to furnish the timber necessary for making rafts and bridges. In Germany, and countries where wood is very plenty, in order to pass with greater expedition, a general can make use of rafts or flying bridges. Two may be placed, one upon the right, the other on the left, of a bridge built upon piles; by which means three columns can pass at once. It should be observed, that the flying bridges are by no means secure against torrents.

In 1742, count Saxe having beforehand possessed himself of Thonau, caused two flying bridges of rafts, and a great work of redans, to be erected, in which he posted five battalions and some cannon.

On the ninth of September all the baggage passed

44 K

the

the Danube: on the tenth the army put itself in order of battle in two lines, which retired successively toward the river.

The lines passed one after the other; that is, the cavalry at the ford, and the infantry upon the flying bridges.

Six thousand of the enemy's advanced guard were witnesses of this retreat without daring to molest it; so prudently were the orders given, and so exactly executed.

It is in retreats that bridges are most liable to break under the weight of the troops; it is at that time the precautions are neglected, because the danger becomes more pressing, and they are not sufficiently acquainted with the rivers over which the bridges are thrown.

If Cæsar, says M. de Puyfégur, had known there were always floods in Spain at the time of the year he was there, he would have been guarded against the accident which he describes: at the end of this reflection the reader may see the methods he proposes for remedying these inconveniences.

In the following account it may also be seen, that a passage cannot be unfortunate, when it is executed by resolute soldiers under the command of a prudent and intelligent general.

After the battle given the 16th of July 1746, under Placentia, the combined army of France and Spain, posted on the other side of the Po, subverted at the expense of the Milanese, and by means of the communications of Lody, drew provisions from the Venetian territory: the Austrians, to the number of 12,000 men, attempted the passage of the Po, foiled by the king of Sardinia with 30,000 men.

The combined army advanced upon the Ambro, to dispute the passage with them; for that reason a very vigorous defence was resolved on upon the lower part of the Ambro: by these dispositions they found themselves constrained to attempt the conquest of Lody, a place of no great consequence; nevertheless, as Lody was the only pass by which the combined army could draw provisions from the Venetian territory; and thro' the apprehension of being a second time shut up in Placentia, where there was no longer any provision remaining, M. de Maillebois proposed the repassing of the Po; and notwithstanding the objections which this proposal already had experienced, and still had to meet with on the part of his royal highness the Infant, it was carried in the affirmative.

It was therefore resolved to pass the Po upon three bridges, on this side of the mouth of the Tydon, the night of the eighth or ninth of August.

The viscount of Crussol was ordered to abandon Lody, which was greatly straitened by the enemy, the night of the seventh or eight. On the eight at night, the retreat having served by way of general, each body put itself in motion.

A body consisting of 8000 men, under the command of M. de Campofaneto, was appointed to keep back the king of Sardinia's army, and to form the rear-guard.

The marquis de la Chetardie, major-general, with 30 companies of grenadiers, 6 battalions, 500 horse, and 6 pieces of cannon, formed the advanced guard: he was ordered to throw a bridge over, and to occupy

the Tydon, whilst the marquis de Monteynard, brigadier, with 4 companies of grenadiers, 3 battalions, 500 horse, and 2 pieces of cannon, landed on the right, to close up the interval between the Po and the Tydon, and oppose the detachments of Piedmontese and Austrians, distributed upon the right bank of the Po, as far as Parpenza.

On the eight, at night-fall, the body commanded by M. de la Chetardie came out from Corte St Andrea, and took post upon the left bank of the Ambro, where he was to embark part of his troops, whilst M. de Monteynard, who came out from Albaroni, embarked with his whole detachment upon the shore upon the right: the Croats were pontoned beforehand, and placed two and two in the mouth of that river.

These dispositions being made at midnight, M. de la Chetardie gave orders to march out half an hour after, in order that the remainder of the body which he conducted, and which had not been able to embark, might arrive at Buttaroni di Sotto, in the place where the bridge should end on the other side.

At one o'clock at midnight, the 68 boats which were to form the two first bridges, left the Ambro in two columns.

There were but 12 grenadiers, or volunteers, killed or wounded in the embarkation; the first bridge was completed at day-break, the second two hours after; and the third, which reached as far as Placentia, was finished at noon: the army, followed by its whole baggage, 4000 mules, 1000 waggons, and 60 pieces of cannon, passed that day and night.

M. de la Chetardie, with his advanced guard, occupied the Tydon from its mouth as far as Verati, after having caused the bridge which belonged to the enemy upon the lower part of the Tydon to be burnt; to which place M. de Nogent went.

The marquis de Pignatelli was ordered to occupy the Tydon from Verati to the Strada Romea; but not having a sufficient number of troops, he contented himself with occupying a casine, which was within musket-shot of the Romea. The marquis de Seneffere having joined him, and knowing the consequence of guarding the country up to the Romea, took the right of M. de Pignatelli, with the body under his command; but his body of troops, joined to that of M. de Pignatelli, not being considerable enough to occupy the ground necessary, he contented himself with reinforcing those troops which the Spanish general had sent into the casine.

M. de Monteynard drove the enemy from Perpenza, whilst a Spanish detachment advanced up to Castel St Giovany.

The order was given to march on the 10th at day-break: the enemy perceiving that the right of M. de Pignatelli did not reach to the Romea, began their attack in that part at eight o'clock in the morning.

M. de Pignatelli, pursuant to the orders of marshal de Maillebois, with his grenadiers, occupied a little rising, which was in a creek formed by the Tydon, and which commanded the opposite shore.

The fire of the grenadiers stopped the enemy for a moment, and gave time for M. de Seneffere to advance with the two brigades of Anjou, and the Lorrain guards, to cover the causeway of Castel St Giovany; upon which he caused the piquets of this last brigade,

to take post in the cassines on the right and the left. He caused messieurs de Larnage and de Saulx to pass to his left, with the brigade of Anjou behind a hedge, which favoured his fire.

The first effort of these two brigades forced the enemy to repass the Tydon in disorder, pushed on the left by the regiments de la Reine, the Saguntum Spanish dragoons, and by a squadron of Dauphiny.

The enemy being formed again, passed the river near the great causeway, came out in a column upon the cassines, which were occupied, and forced the piquets of the Spanish guards to give way: then M. de Senestre caused M. de Wigier to march with the brigade of Lorrain guards, commanded by the chevalier de Beauveau, which retook the cassines, and maintained itself there till the piquets, obliged to give way by the fire of the enemy's column, left our right and the cannon uncovered; then the Lorrain guards retired in good order into their former posts.

By a motion to the right, which half the brigade of Anjou made, it took the enemy's column in flank, which wanted to get before the brigade of Lorrain's guards, stopped it, and mixed itself with it.

Three squadrons of Spaniards caused it to fall back upon its cavalry; then the brigade of Lorrain guards returned to take its post; it received orders to march, to attack a battery of four pieces of cannon; but the Spanish cavalry which was to sustain it, not being able to bear the fire which it received, threw the brigades into confusion, who very soon regained their ground, and maintained it, till they were relieved by the Spanish guards, sustained by all the French cavalry under the command of M. d'Argouges: at last the enemy was obliged to retreat behind the hedges.

Whilst the prince de Beauveau occupied the castle of Verati on the left, M. de la Chetardie, who sustained that village, drew near to the left of M. de Pignatelli, who had been joined by the Waloon guards and the Provincial grenadiers. M. de la Chetardie wanted to charge the enemy with bayonets: M. de Pignatelli opposed it; but the French general kept up so continual and great a fire, that the enemy's grew less and less, and at a greater distance.

Things remained in this situation till two in the afternoon, when the retreat was ordered: M. de la Chetardie caused M. de Beauveau to advance with 30 companies of grenadiers and a regiment of dragoons, to guard the great causeway: his appearance stopped the enemy, and M. de la Chetardie continued his march without being molested.

The body which came out of Placentia, along with M. de Castellar, retook the ground where our troops had fought: the enemy repassed the Tydon, and M. de Castellar fell back upon M. de Beauveau with his grenadiers.

The passage of the Po, and the battle of Tydon, are two actions worthy of being handed down to posterity, from the readiness, resolution, and steadiness, with which they were executed.

The passage of the Po, by the assistance of three bridges, was executed in 24 hours, notwithstanding the great quantity of waggons which the Spaniards caused to pass by force. The action which followed this passage, is a lesson for every military man, upon the manner in which he must form after a passage. The

passage of the Po was effected betwixt two armies of the enemy, and under their eyes; the enemy were terrified at the steadiness of the troops, and the prudence of the generals.

The success of the day of Tydon is partly owing to the marquisses of Senestre and Pignatelli, under the orders of marshal Maillebois.

In a word, a general cannot take too many measures in the passage of a river, or sufficient precaution to prevent the enemy from passing, nor make use of too much contrivance or artifice in a retreat; and he should even employ cunning itself, when the enemy is superior in strength, particularly when he harrasses the troops.

It is impossible, says M. de Montequieu, to give a detail of every thing without tiring the reader; it has therefore been thought better to cite authors, whenever it has been imagined that the reader would find in their works solid instructions, which it would be useless to repeat here: but it has again been supposed, that it will convey pleasure to the military readers, in placing before their eyes examples, of the most part of which they have been witnesses; a method more conducive to instruction than all the rules that can be given.

SECT. XI. Of Battles.

Of all the operations of a campaign, the most important, and that which is most deserving of attention, is a battle, because it is generally decisive; every other operation is but preparatory to, or consequent of it. A general engagement, says Vegetius, is often decided in two or three hours; after which there scarcely remains any resource for the vanquished. Battles, says M. de Montecuculli, bestow and take away crowns; from their decisions princes cannot appeal; by them war is put an end to, and the name of the conqueror immortalized. A general should, therefore, think of, and try every thing, and should leave nothing unattempted, before he proceeds to this last extremity.

A general should by no means suffer himself to be forced to a battle; neither should he offer it but when there is a real necessity for it; and even when he gives battle, it should be rather with an intention of saving than shedding blood; more with a view of asserting the rights of his master, and the glory of his country, than of oppressing mankind.

However bloody a battle may be, it is always less so than a long war; which, by reiterated troubles, consumes the treasures of sovereigns, that finew of a state, and drains the blood of the subjects. Nevertheless, there are some occasions where it is not left to a general's choice, either to give or accept of battle. An army of observation, and an army acting on the defensive, neither can nor ought to be desirous of coming to action. Both the one and the other should have no other object in view, than that of posting itself in so advantageous a situation, that the enemy may neither entertain a thought of attacking it in its camp, or any hope of forcing it. The army of observation, whose only object is to protect, or to cover the troops forming a siege, should never seek to fight the enemy, unless attacked by him: the other, obliged by its want of strength to act upon the defensive, should only be desirous of occupying advantageous posts, to prevent the enemy's penetrating into the country, and attacking it in any position it shall have taken.

If the choice is left to the general, he ought to be particularly careful, before he comes to a resolution of giving battle, to examine whether he can gain greater advantage by winning it, than he will sustain damage by losing it.

It is therefore, neither caprice, nor a mistaken courage, or the desire of distinguishing himself at an improper time, that should determine a general to give battle. "The reasons which should induce a general to give battle, are," according to Mr de Feuquieres, "his superiority over the enemy, both in the number and quality of troops, the enemy's incapacity, his ill-chosen encampments and negligent marches, the necessity of securing a place, or the certainty of a reinforcement, by the junction of which the enemy will become superior, or circumstances which may change the original designs of the campaign." This was the reason which induced the viscount Turenne, in 1674, to give the battle of Einshelm, because the prince of Bournonville waited the arrival of the elector of Brandenburg, who was coming to join him with a considerable reinforcement; and if he had not given battle before that junction, the enemy's army would have had a very great superiority over his. The reasons given by Montécuculli for avoiding a battle are, "when the loss of it will be more prejudicial than the gaining will be advantageous; when inferior to the enemy, or when success is expected; when the enemy has the advantage of the ground; when it is perceived the army is working its own ruin, either by the fault or division of the commanders, or through the disagreement of confederates." It may also be added, when the enemy's army labours under some disease; when it is in want of provisions and forage; and that, disheartened by these circumstances, his troops desert from him.

It is on a day of battle that it becomes particularly necessary for a general to be acquainted with his own ground, and also that which is occupied by the enemy; to know in what manner his wings are supported, the nature of the places where these supports are; whether he can be surrounded, and in what part he can be attacked with the greatest facility.

But however essential these branches of knowledge may be, it is not always the superiority of number, or quality of the troops, or advantage of ground, that will secure the best disposed army from being routed: it is the foresight of the general in the precautions he has taken before the battle; it is his genius, his activity, his coolness in the time of action, and the capacity of the general officers acting under him, that determine the success.

Ground, seemingly the most advantageous, often presents obstacles, which do not immediately strike a general, although an experienced one, and which may prove fatal in the course of a battle; how, therefore, will a general be able to correct these mistakes, if he considers them as only trivial? At the battle of Cerignoli, given on the 28th of April 1503, the enemy's front being more extended than at first it was supposed to be, in order to give a greater extent to that of the French army, it was necessary to continue the lines across vineyards and thickets; by which means, the neglecting to fill up a ditch caused the defeat of the

French, and the death of M. de Nemours their general.

A general should not always pursue his own opinion, it being impossible for one man to see every thing; he should, therefore, cause an exact account to be given to him of whatever he cannot have an opportunity of seeing personally; to inform himself by spies of the enemy's order of battle, and act in consequence of that knowledge; he should possess himself of all places capable of containing ambuscades, which he ought to have had examined some days before the battle. Santa-Cruz hath given a particular detail of all these preparations.

It is in these moments, which decide the fate of whole nations, that the genius and prudence of a general ought to be conspicuous; he should, at the same time, see what is doing among his own and the enemy's troops. Beside the precautions which ought to have preceded the day of battle, those which ought to be taken in the course of the action are so numerous, that it is impossible for them all to find a place here.

Some depend upon the general's ability, others upon circumstances, which it is almost as difficult to describe, as to mark out the necessary dispositions for them.

It depends upon the general's genius and foresight to make choice of intelligent, active, and prudent aides-camp, to assign to each particular body the properest to command it; not, for example, to place, at the head of infantry, one who has been long accustomed to the service of the cavalry; or, at the head of cavalry, one who is more used to the infantry, &c. to encourage the soldiers by the hope of rewards, and by motives which may spirit them up, and to threaten those who are so unmanly as to tremble at the sight of an enemy, or rash enough to run forwards without order.

The general should also be capable of forming new schemes, in order to render those of the enemy abortive; he should also take care, whatever may be the nature of the country, to dispose his army after such a manner, as to render it equally strong in every part, and that each body may protect and assist one another without confusion; that the intervals necessary for acting are well preserved, and that the reserve can easily march wherever it shall be ordered: in a word, the troops should be disposed after such a manner, that even before the action they may perceive in what manner they are to act.

It is the work of genius to take advantage of circumstances, and to submit to them; it is impossible to foresee the precautions dependant on them, as the very circumstances must be, themselves, unforeseen: it is by a general's address, in knowing how to profit by circumstances, that he sometimes make a motion, conducive to the whole success of the action, from the inequality of the ground, a sure means of beating him. M. de Montécuculli reduces all the advantages that can be gained over an enemy to four principal heads, which, in reality, are of themselves reduced to the knowledge of profiting by circumstances; such are the advantages of number, when the enemy is beaten in his posts, his convoys, and in his forages; when an ambuscade is surrounded, or when a whole army falls upon a small, weak, and separated body: the second head consists in the knowledge of the commander; the

third in the manner of fighting; and the fourth in the advantage of the ground. A general, who properly considers these heads, will dispose of a combined army after such a manner, that it may, at the same time, receive orders without mistake, and execute them without confusion; a very necessary precaution, and one which Hanno, general of the Carthaginians, neglected to take with regard to the strangers allied with them, which occasioned the troubles related by Polybius. He should have mixed the soldiers belonging to those countries, where bravery is in a manner natural to them, with those belonging to countries where it is more extraordinary.

Notwithstanding, Tacitus would endeavour to prove that it is much better to keep them together; because, says he, each different nation, striving to distinguish itself, will be animated by a desire of excelling each other: experience, however, has often proved the contrary:

Vigétius points out the precautions necessary to be taken by a general, to avoid having either the wind or the sun in his front. The wind, which raised the dust, and blew it into the eyes of the Romans, contributed to the loss of the battle of Cannæ: the sun, on the other hand, dazzles the soldiers, and lays open their dispositions and evolutions to the enemy: in a word, the general should not even neglect those precautions which may be in appearance useless, whether before the battle, or at the very time they may be put in execution after the action; as the rallying the troops, the refreshing of them, the retreating from before the enemy, or the pursuit of him, supposing the battle to be gained. A general should have beforehand formed the plans of the marches and the enterprises he would attempt, and be almost certain of the means of executing them; if, on the contrary, he fails, he should have determined the positions by which the army, fixed in a camp strong by situation, may prevent the enemy from reaping any great advantage from his victory: he should also have provided for the security of the prisoners, the hospitals, the plunder of the soldiers; in short, for all that is necessary for preserving order and discipline, and every thing contributing to the security of the troops: the distress of the enemy, and the glory of the sovereign, should be provided for without waiting for the event; for at that time confusion and disorder would prove more fatal than even the battle.

In the treatise written by Santa-Cruz, upon the dispositions before and after a battle, may be seen a long detail of the precautions depending upon genius, and of those which are regulated by circumstances.

The general's post during the action ought to be, according to Vigétius, on the right wing, between the cavalry and the infantry. Onoander fixes it upon some height, and Santa-Cruz towards the centre, in the front of the second line. Titus Livius and Polybius have observed, that the posts of Scipio and Hannibal were always in those parts which were least exposed; because, as observed by Onoander, a general who runs into danger is a rash man, fuller of presumption than courage: neither is daringness, adds his commentator after Plato, always a sign of courage; besides, a man who is really brave, is never daring but when it is absolutely necessary. Æneas, all valiant as Homer has painted him, did not judge it proper to

wait for Antiochus, who had joined Menelaus, with whom he was fighting.

A general should not always suppose that what particularly strikes him is right; he should reason calmly upon the probability of it, in order to come to a greater degree of certainty with regard to the practicability: he ought also, says Vigétius, to be acquainted with the nature of the enemy, and the characters of his generals, whether they are prudent or rash, daring or timid; whether they fight upon principles or at hazard: in effect, a general ought to be earlier or later in making an attack, in proportion to the rashness of the enemy. If, says M. de Montécuculli, any sign of fear or confusion is perceived among the enemy, which will be known when the ranks are disordered, when the troops mix together in the intervals, when the colours wave about, and the pikes shake all at the same time, then he should charge and pursue the enemy without giving him time for recollection: some dragoons, light cavalry, platoons, some loose troops, should be sent forward; who, whilst the army advances in order of battle, will go before to seize some posts into which the enemy must fall. A general also ought, says Vigétius, to sound the spirit of his soldiers, and observe whether they have a firmer countenance than the enemy. It is dangerous to lead an army on to action that is not thoroughly determined to do its duty. "Battles," says Vigétius elsewhere, "are generally won by a small number of men." The great mystery consists in the general's knowing how to choose them, to post them well, conformable to his plan, and the services required of them.

I cannot assign the reason, says he, why particular bodies fight better against other particular ones, or why those who have beat bodies stronger than themselves, have in their turn been often beaten by those that were weaker? It is undoubtedly owing to want of confidence; because the place of action has been different; or from other circumstances which cannot be laid hold of, but on the very instant. The situation of the mind is shown in the countenance of the soldiers; it is declared in their discourse, and by the most trifling of their actions. The general should consult them; he ought even to go farther; the best countenance is not always a sign of the firmest courage. Cowardice often conceals itself under the mask of intrepidity; but soon as the action begins, the veil falls off, and the coward shows himself, notwithstanding all his endeavours to the contrary. Neither at this time should a proper degree of fear be thought blameable; nature must be allowed to shrink in that awful and uncertain situation: the coward gives himself up to his fears; the bully seeks in vain to dissimble them; and the rash man, who can neither distinguish between danger and safety, is sensible of both; the real soldier is always modest, and contented with having done his duty. A good general turns every thing, even want of strength, to advantage. Hannibal, at the battle of Cannæ, posted his best troops upon the wings, that the centre, which was composed of those on whom he had the least dependence, might be the sooner broke, in order to give the wings an opportunity of surrounding the Romans.

It also requires a very strict examination in a general, in order to be thoroughly master of the circumstances on which he should regulate his dispositions; and

and he will also find it sometimes necessary to make some change in his original intentions. It is always proper that the corps of reserve should be composed of veterans, and even of part of the flower of the army; for should the army happen to be broke, this reserve alone may probably give a new face to the action: it was this method which Hannibal pursued at the battle of Zama; where Scipio, after having defeated the troops which presented themselves to him, was astonished to find he had a new army to fight with. At the battle of Fontenoy, the household troops placed in reserve, with some brigades of infantry, determined the success of that day. Nevertheless, on some occasions this disposition may prove disadvantageous; such, for instance, where it would be necessary to present a large front to the enemy, or where it is necessary to prevent his getting possession of a pass or a defile; where a general finds himself too inferior, and where there are also posts to be defended.

It would be unnecessary to repeat every thing mentioned by Vegetius, relative to the precautions necessary to be taken before a battle; time, and the difference of weapons, have greatly altered dispositions: firearms, which are now made use of instead of darts and slings; the bayonet, instead of the pike, have contracted the intervals which must necessarily be left between every soldier.

The emperor Leo carries his speculations still farther; he exhorts a general to continue the action with the enemy, according to circumstances of times, seasons, and constitutions: in effect, there is no degree of equality between an army fatigued by a long march, and an army which, although inferior, has been at rest. Soldiers transported from one climate to another, are no longer the same; the southern people, naturally weak, are much more so in a northern country; and the northern people sicken in a more temperate climate. This truth has been often confirmed by the experience of almost every nation; particularly by the French in many of their wars in Italy; and lastly, in their campaigns in Bohemia.

It is upon these circumstances, and upon many others also, which it would be too tedious to particularise, that a general should regulate the dispositions for a battle. Vegetius mentions only seven different methods, which may be nearly reduced to three: "The first method of ranging an army in order of battle is," according to him, "the long square; the second, by marching obliquely with the right to the enemy's left; the third, by beginning the action with the left against the enemy's right; the fourth, by pushing on the wings against those of the enemy, when the armies come near each other, leaving the centre by the way (which was Hannibal's disposition at Cannæ), and by trying immediately to break through the enemy's wings contrary to his expectation." The fifth is like the fourth, or rather the correction of it; because by means of it the centre is concealed, and covered by the archers and light-armed troops. "The sixth resembles the second; when the army in order of battle draws near to that of the enemy, and with the right attacks his left briskly, where the action is briskly maintained with the best troops, by keeping the rest of the army at a distance from the enemy's right, and disposed long-wise like a javelin that presents its point. The

seventh is, when the army can form with one wing to the sea, a river, a lake, a morass, or an hollow; and that the general reinforces with the best troops the wing that is not supported."

The chevalier de Folard and M. de Puyfégur have themselves also conceived particular dispositions; which, however suppositions, still show the greatness of their genius, and give great perspicuity to those principles they have established in their works; and although it may never happen that every circumstance which they have supposed should actually meet together, there are nevertheless cases where there may be found a very near resemblance of them, and where their imaginary dispositions may be put in execution. But even should these suppositions have no other advantage than that of exercising the genius of an officer, who takes pleasure in his business, to infuse into him that spirit of contrivance, so necessary for one who is placed at the head of an army, and the facility of readily applying rules to circumstances, and theory to practice, they well deserve the praises of posterity.

The order and disposition of troops for action depend entirely upon the general, who knows how to profit by circumstances; the just execution of them depends upon the capacity of the general officers. The general cannot be every where, or see every thing; he is obliged to rely upon the understanding of those who command under him for the just execution of his orders; the general officers should know how to vary them, in proportion as circumstances, and the situation of the enemy changes. They should have an exactness and quickness of eye, both to oppose and profit by them; and, as M. de Puyfégur observes, the disposition of the troops being once regulated by that of the enemy, by the situation of the country, and the general orders that have been delivered, the only part the general can have in the action, lies in those places where he is within reach of giving orders himself.

M. de Montécuculli with great reason observes, that there cannot be too many officers in an army on the day of battle, in order to supply the places of those who are killed: but can a man possessed of any degree of humanity approve of what he adds, that this number should be increased in time of war, and reduced in time of peace? What a prospect for a soldier, who, after having lavished his blood for the safety of his country, and the glory of his prince, sees himself exposed to the fate of Belshazzar! Whatever were the virtues of his master Justinian, can any one, without indignation, see this general, after having overcome the Persians, reunited Africa to the empire, punished the Vandals, driven the Goths out of Italy, ravaged Assyria, scattered at a distance from both empires that throng of barbarians by which they were over-run, and preserved the throne, and the life of the emperor; upon the bare suspicion, or rather under the pretence of a conspiracy, deprived of light, and reduced to beg alms of passers, in the streets of that city which he had so often saved?

It has been already seen, that the dispositions in a mountainous country change according to the situation of the ground. Vegetius repeats, speaking of a field of battle, what has been so often established in the foregoing sections, that an open country is always most advantageous for an army that is strongest in cavalry;

vairy; and that an enclosed spot, divided by ditches and marshes, covered with mountains and woods, is most convenient for infantry. In this last, the knowledge of the country, the art, the ability of the general, and the understanding of the general officers under his orders, sooner ascertain the success, than a superiority of troops in an open country, which presents little or no variety of ground, and which allows the greatest part, or indeed the whole, of the troops to act; the superiority in troops is attended with great advantage, provided also the disposition is good.

The different disposition for troops are so many, the circumstances differ so greatly, that were it even possible to connect in one body only, all the battles which have been fought since the time mankind resolved to regulate their properties by the law of the strongest, the number of contrivances which remained to be collected, would be greater in number than those which have been executed. It is impossible to give a detail of every thing; every particular spot, and the disposition proper for it, every country, and all the circumstances that may oblige these dispositions to vary, must be described. Those now going to be mentioned, are only with a view of giving the rules, and of more clearly demonstrating those precepts which lead to the knowledge of all others.

DISP. I. Let two armies of equal force be supposed, in an open country divided by a river, consisting of 57 battalions and 72 squadrons each, cavalry, hussars, and dragoons. The two armies are on the same side, the right of the one, and the left of the other, to the river. The left of the army whose right is to the river is unsupported; and that whose left is supported, has a wood on its right. By this disposition may be seen the necessity of covering the wing of the army A, that is exposed.

The army I, whose right and left are supported, is formed upon two lines, and presents the same front as the army A, with a reserve in the rear. The following is therefore thought to be nearly the disposition which should be made by the general commanding the army whose left is unsupported. It therefore seems, that in order for a safe disposition, the first line ought to consist of 20 battalions, with intervals of about three toises between each battalion; 12 squadrons on the right, with their proper intervals; four battalions on the right of the cavalry, 10 pieces of cannon, and a battalion in column close to the river; 12 squadrons on the left of the first line, with their proper intervals; 16 battalions in the second line, 300 paces distance from the first; 11 squadrons on its right, placed behind the intervals of those in the first line; and on their right, six squadrons of dragoons next the river, in order to sustain the infantry and cannon covering the right; 11 squadrons on the left, placed in the same manner as those on the right; 10 pieces of cannon, supported by a battalion in column, between the infantry and the cavalry of the right; 10 others, supported also by a battalion between the infantry and the cavalry of the left; four battalions in the rear of the second line on the left, with orders to transport itself obliquely, or sideways, as soon as the army moves to attack that which is drawn up against it; 12 squadrons of cavalry in the rear of the first line upon the left, to post themselves obliquely upon the

flank, at 100 paces distance from the first squadron on the left, next to the four battalions and the cannon; the reserve, consisting of 10 battalions and eight squadrons of dragoons, in the third line upon the left flank, so that it may fall into the first line as soon as the squadrons of cavalry, which were in the rear of those of the first line, shall be posted obliquely: in this position, the army will move forward, the right never quitting the banks of the river.

If the enemy's army should advance, the disposition of the army A will become still better, because the army I will quit the support it had on its right; but if, on the contrary, it remains in its post, in order to keep this support, then the 10 battalions of the reserve, followed by the eight squadron of dragoons, will join the four which support the flanks of the cavalry which is posted obliquely. When marching, this line posted sideways should proceed obliquely; and when the cannon shall be near enough to cannonade with effect, it should make several discharges, in order to break and beat down the entrenchments, or felled trees, which the enemy may have made, and also to destroy their disposition. As soon as the army A shall be near enough to cannonade the army I with success, it must halt, and amuse it with a continual fire of the cannon. The principal attack ought to be made at the wood by the 14 battalions: in order to give more strength and certainty to this attack, six other battalions, with 10 pieces of cannon, should be detached to it from the second line, always keeping up a fire from the front. If during this attack, it is perceived that the enemy weakens his line, in order to carry assistance to the wood that is attacked, then the centre and the right of the army should march up, and charge him briskly. The troops who cannonade the wood ought not to advance, but should only keep the troops posted in it at bay; because that part which the enemy has weakened will then become the principal attack: it is probable, that the enemy having weakened his front, will certainly be broke. If the enemy should not weaken his front, and the attack of the wood should succeed, as soon as the enemy is driven out of it, the troops which attacked it should take the enemy in flank; then the body of the army, by advancing, ought to determine an affair already half gained. If by the intelligence the general hath received, and the number which he knows the enemy's army to consist of, and which he sees before him, he judges the wood is filled with infantry, and that consequently the attack of it will be attended with difficulty, he must attack on the side of the river, by marching by degrees from the right, as if to sustain the left. In order for the greater certainty of succeeding in this attack, he should reinforce the five battalions upon the right with some others from the second line: the left should continue in the position already mentioned, to keep back the enemy. If it should happen that the enemy, seeing his left attacked, causes the troops to leave the wood in order to replace those of the centre, which he caused to march to the assistance of the left, the 14 battalions which are posted sideways, ought briskly to attack the wood sustained by dragoons. These last should post themselves upon the left flank of the infantry in order to cover it; and as soon as it shall be within 60 paces of
the

the enemy, it should march up to him with bayonets fixed; and the dragoons ought to attack him in flank, at the time the infantry does the same in head. The wood is all this while supposed to be practicable for the dragoons on horseback; but in case it should not be so, they must dismount, the infantry being sufficiently supported by the 12 squadrons of cavalry, which are placed sidewise.

The general may with ease, especially in an open country, attack the enemy's whole army together; but this may be attended with great danger, and if the whole front of the first line is broken, there will not be much difficulty in breaking the second: whereas, by attacking the enemy's army in one or two parts, if one of these attacks succeeds, the battle is won; because the troops who are victorious, take the enemy in flank, at the same time that he is attacked in head by the rest of the army. In case it should not succeed, the troops who made the attack can retreat, protected by the whole army, which hath not at all suffered.

The general should, as much as possible, conceal the motions he intends making from the enemy; consequently, the five battalions and 10 pieces of cannon which support the right of the army next the river, ought to march in the rear of the squadrons of the first line, the infantry with their arms secured, and not range themselves in the order of battle intended, till the two armies are ready to march to charge each other. It is the same with regard to the squadrons of cavalry, which should be posted behind those of the first line, to execute the design already laid down. See Plate CCXCIV.

DISP. II. If the two armies are not supported either on their right or their left, the same position should subsist that hath already been established for the cavalry, which is in the rear of that belonging to the first line, except that it should be distributed on the right and the left. If there is not cavalry sufficient, hussars must be substituted in its place; but if there should be cavalry enough, it must be used on this occasion; because cavalry being a greater body, its charge is heavier, and it also makes a greater impression upon other cavalry opposed to it, provided they execute their order with great quickness. This cavalry or hussars, which are posted sideways, should not quit their post, but wait the success of the attack. If the enemy is repulsed, they must then fall upon his flanks, and by a brisk and vigorous charge endeavour to involve the second line in the confusion of the first; they will be followed by part of the wing of cavalry that is victorious, in order to give a greater force to the attack of the second line, taking as much care as possible not to leave any body of cavalry upon the wing of infantry that is in a condition of protecting it. After these two lines of cavalry have been broken and pursued, half of the victorious line should remain in order of battle; and, by a motion to the right from the left, take the enemy's infantry in flank, at the same time that it is attacked in head by the infantry of the army. The second line should then move into the place of the first, in order to be near enough to assist it in case the enemy's infantry should stand its ground firmly; but it is probable, that being deprived of its cavalry, it will neither have the same firmness, nor the same spirit, as if it was support-

ed, especially when it is attacked on every side.

The cavalry and the hussars who pursue the beaten wing should not expose themselves too much, or break their order in the pursuit, for fear the enemy's hussars which are behind should fall upon and beat them by attacking them on all sides; which may very probably happen, if they do not take care to keep in order of battle; which should at least be attended to by the cavalry. After the hussars have pursued the enemy's cavalry so long as to entirely disorder them, they should return and take their former posts, in order to march from thence to whatever place they may be serviceable. Although it may appear something hard to make the hussars return, there is nothing so difficult but what may be accomplished, when order and discipline are firmly established, and when an officer has the art of making himself obeyed.

At the battle of Cannæ, the Carthaginian army, superior to that of the Romans, having broke through them, one part continued the pursuit, and the other fell upon the rear and the flanks of their infantry; at the same time the Carthaginian infantry charged that of the Romans in all parts, which decided the victory. Thus Hannibal owed his victory partly to his superiority in cavalry, and to his attack upon the flanks. The Numidians, who were upon the right wing of the Carthaginian army, and who fought nearly in the same manner as the hussars, performed on this occasion the same service as the hussars would certainly do in the disposition now before us; so true it is, that infantry, destitute of its cavalry, hath no longer the same firmness, nor the same spirit; and if it is also attacked in head by infantry, it cannot avoid being beat. The principal attention of a general, says M. de Montécuculli, ought to be to secure the flanks; experience having taught, that when the wings of cavalry are broke, the infantry is easily surrounded, and hath no longer the means, nor even the courage of defending itself. The reader may see the principles he lays down upon that subject. It is seen by the example of the battle of Cannæ, what use the cavalry ought to be put to, particularly in an open country where it can easily act. What advantage may not be expected from it, when an army of Romans, 80,000 strong in infantry, and 6000 horse, was overcome by the Carthaginians, weaker by the half in infantry, but which derived its principal strength from 10,000 cavalry, all veterans, and well disciplined.

It is the manner of drawing up troops, their order and discipline, and not numbers, by which battles are won; it is very rare that the whole can be employed. During the late wars on the continent, scarcely the half have been engaged in all the battles which were gained.

But if the wing of cavalry is beat, it ought to retreat with as much order as possible. The cavalry, or hussars, that are posted sidewise, should always continue in the same place; there is no reason to fear that the enemy will advance briskly to the pursuit; because he will be taken in flank by the body that is posted sidewise; a circumstance which ought not only to abate the eagerness of the conquerors, but also animate the conquered. By this manner of acting they gain time to pass through the intervals of the second line, and to rally in the rear of it, which they can perform with the

greater

Plan of an Order of Battle 1st Disposition.

greater ease, as they are neither pursued or molested, at least but very lightly.

In order to prevent the inconveniences that may arise if the hussars in charging the first line of the enemy in flank are charged by the second, it is necessary to detach instantly from the reserve a body of dragoons sufficient to fill up the intervals of the hussars, which will form a full line without taking up more ground: this can be so much better effected, as there would be no ground on the other side of the troops who are posted sidewise, and that, besides, these troops would be at too great a distance from the main body of the army.

Again, without causing them to fill up the intervals of the hussars, they may be placed in a second line behind them; and when the hussars attack the flank of the enemy's wing, the dragoons will take their place, in order to keep back the enemy's second line. This method hath the same effect, and is performed with less difficulty. It is almost evident, that the second line will not dare advance to protect the first for fear of being charged in flank by the dragoons, but that on the contrary it will be obliged to retreat.

This disposition, the performance of which appears very difficult, is not in reality so, if the general hath taken the necessary measures, and if his troops are well disciplined, and know how to move with order and exactness. Even when this motion is not performed with all the exactness possible, it can never be dangerous, because the front of the two lines will not be destroyed, and because it is also made upon the rear; and that if the dragoons and hussars are attacked and beat in marching up, their defeat cannot be any way prejudicial to the main body of the army. When the field of battle is in an open country, all the troops generally come down, especially when there is no obstacle to prevent them.

On these occasions, it is requisite that the disposition of the troops should be strong in every part; there should always be a reserve, whether of infantry or dragoons, in order to be ready to assist the troops which have suffered.

If it is possible, in an open country, to find any hollow to support the right, and a village to support the left, the general should make choice of that situation, supposing his intention is to accept, and not offer battle. If he designs to give battle, it would be unnecessary to take this position, because he must quit it in order to attack the enemy: but if circumstances require his accepting it, he must seize this post, and place infantry and cannon in the village, and station other infantry in the rear to support that which is in the village.

As to the disposition for the order of battle, especially for the front of the line, it must be regulated by the ground, by the disposition the enemy has taken, by the troops that can most easily act, and by those that the enemy can oppose to them.

If the enemy has pitched upon a field of battle, and the general would attack him in it, he should keep his whole front employed; but should make his chief efforts on one or two parts, upon the wings, or at the centre. This was the method practised by marshal Saxe in all his battles: when he accepted battle, as he was obliged to do at Fontenoy in 1745, he was in ex-

pectation that the opposite army would attack him on one side sooner than another; in this situation the dispositions should be properly regulated, the posts intrenched and occupied, the cannon distributed, and troops placed in the rear of each post to sustain those which are in it: victory should then be expected from the capacity of the commanders, the firmness of the troops, and the assistance that is properly given them. But when a general gives battle, he may attack either the right, the left, or the centre, always conforming to the situation of the ground, and the field of battle which the enemy has chosen, which cannot be ascertained but by a thorough knowledge of the country.

It is dangerous to attack the whole front of the opposite army with equal vivacity, because, if the attack does not succeed, the troops are disheartened, and are witnesses of each other's defeat. If the first line is repulsed, the second is seldom of any great use; whereas, by only employing the whole front of the enemy, and making a strong attack upon one or two parts, and it is successful, the troops can take the enemy in flank; and those which amused his front will then attack him briskly, and prevent him sending assistance to the troops that are beat. If the general does not succeed in the first attack, he can try it again with greater force, by causing the troops of the second line to march, as was done at the battle of Lafeldt fought in 1747: the French troops being repulsed four times, M. Saxe sent them a reinforcement; these troops being united, carried the village at the fifth attack, which determined the fate of the battle.

In a plain but inclosed country, a general can attack only part of an army. Antiquity furnishes many examples of this. Epaminondas, at the battle of Leuctra, attacked only the right of the Lacedæmonian army, with a large column of infantry that formed his left; causing the right to be supported, and making the left march, the whole army, according to the opinion of the chevalier de Polard, wheeled. The battle of Mantinæ, won by the same general, is also of the same nature; with this exception, that it was the centre of the Lacedæmonian army that was attacked. These examples are only proposed as what may possibly happen, but which it would be dangerous to imitate on every occasion, and which should be pursued in circumstances only where a general expects great advantage from them.

As the cavalry can easily act in an open country, and be of great assistance to the infantry, all possible means should be used to contribute to the success of their attack; they should always be supported by troops in their rear. Cavalry is of great use, particularly where the two armies, from the situation of the country, find no obstacle to prevent their joining; and if the cavalry, as M. de Puyfégur observes, is beat, even when the infantry of the same army is victorious, the best thing that can afterwards happen to it is, to retire in good order.

The ground so often varies, that even in an open country there are unevennesses, thickets, morasses, and hollows; in each of these situations the dispositions should be changed. If these thickets happen to be in the line of cavalry, and it can act there, (for if it cannot, it would be a very great fault to place it in them) it should be intermixed with platoons of infantry, ob-

serving also not to take them from the main body of the army, but from the reserve, in order not to diminish the strength of the front; which should never be done on any occasion whatever, unless part of the army, either by its own or the enemy's position, cannot act offensively, by reason of some morass, hollow, or any other obstacle that the enemy may have placed before him: if, nevertheless, a general can take an advantageous position, by causing these thickets or these hedges to be occupied by infantry, he should give it the preference, to enable the cavalry to act with the greater facility.

There is great care necessary, in fortifying a place, to get possession of the most advantageous parts, whether by fortifying that which overlooks the plain, or by levelling that which might command the fortifications; so as, in a polygon, every bastion, and all the out-works, flank and protect each other: in like manner troops drawn out in order of battle ought mutually to protect and support one another. Nothing should be omitted, nothing neglected; advantages in appearance trifling, often become decisive.

The dispositions vary not only according to the situation of the ground, but also according to the general's views. Some draw up the battalions without intervals, or like a wall; others, with small intervals; others leave the distance of half a battalion between each; and others, in pursuance of the chevalier de Folard's method, place them in columns.

The first disposition is without doubt formidable, as to infantry; but, as it has been already remarked, it is defective with regard to cavalry. In the third, the interval of half a battalion is too wide: it would require an immense tract of ground; besides, the battalions would not be near enough to have it in their power to protect each other. The second seems better, because the front is not so large, the battalions are more within reach of assisting each other, and have only the distance necessary to prevent their mixing confusedly together. The fourth is undoubtedly very good; but can a general promise himself, that the soldiers can always march at an equal pace together, and without stopping? The fire of the column is continual, it defends itself on all sides; but its oblique fire does not do much execution, and there are situations and spots where this position in column would be faulty. When it cannot approach the enemy, and is also exposed to his cannon, this disposition would be dangerous; because it is certain that cannon plays with much greater advantage upon depth, than upon breadth: besides, not being able to get near the enemy, there are only the heads of the columns able to fire, and the rest remains inactive, exposed to the cannon. The position of the column is therefore only very good, when it can get up to the enemy and charge him.

The marshal de Puyfégur asserts, that an army in an open country, formed in two lines, the first of which is without intervals, ought of course to beat an army that is formed with intervals.

The reason he gives for it is sensible: it being certain, that a full line keeps itself much closer in marching; and that, charging the first line of the army that has intervals, it ought to have broke through it before the second line, which is 150 toises or 300 paces behind, can have time to come up to its assistance;

which might very well happen, and examples of it may also be cited. But could not there be another disposition opposed to this disposition in wall, keeping the necessary intervals, not only capable of resisting it, but also stronger, whether by the position and arrangement of troops, whether by the ready assistance they can give each other, without being confused in their motions?

Let two armies be supposed in a plain country, without support to the wings of either side, or without any obstacle that may prevent their getting up to each other. The enemy's army, as hath already been said, is in two lines; the first of which is formed in wall, both infantry and cavalry; the second is formed with large intervals, and a body of hussars in the rear. The army to be opposed to it is of equal force, and consists of 40 battalions and 54 squadrons, cavalry, hussars, and dragoons. The following seems to be nearly the manner in which it ought to act against the enemy, who is supposed to be drawn up in wall.

The first line of infantry composed of 15 battalions, has the distance of three toises between each battalion, and the distance of half a battalion between each brigade, eight squadrons on the right, and as many on the left, with their proper intervals: 15 battalions in the second line, 200 paces distant from the first, seven squadrons on the right, and the like number on the left, in the rear of the intervals of those of the first line, supporting the infantry of the second; 10 battalions in reserve in two columns, one of which in the rear of the squadrons on the right of the second line, and the other of the same force posted in the same manner on the left; 12 squadrons of dragoons in the rear of the second line, half on the right, half on the left; and 12 squadrons of cavalry, or hussars if there is not cavalry, in the rear of those of the first line.

By this disposition, the army appears to be ranged in two lines, with a reserve, and will leave no room for the enemy to doubt of the motions it may make in marching: this disposition will undoubtedly have that effect, and does not appear very formidable; but as soon as the two armies begin to move forward, the second line of infantry must advance as unperceived as possible, forming itself in columns by battalions, each of which, with its head to a battalion of the first line, will form as many T's. The 10 battalions in reserve, which form two columns of five battalions each, will march and fill up the space on the right and left, between the infantry and cavalry. The cavalry, or hussars, which are in the rear of the first line, one by a motion to the right, the other by a motion to the left, will post themselves sidewise, at 100 paces from the wings of the army; the dragoons must post themselves in the rear of them in a second line. This will be performed much easier marching, because it is not complicated; it is also performed in the rear, and the front of the first line is not put into disorder; and consequently, the enemy will not perceive it soon enough to change his position, and oppose the disposition which is presented to him. This first line, by this disposition, forming as many columns as there are battalions, of course ought to break through the enemy's army which is in wall; but not above four deep, because the impression of a column ought to be much stronger than that of a battalion four or six deep. See Plate CCXCV.

WAR.
Plan of an Order of Battle IInd Disposition.

Scale of $\frac{1}{4}$ a League 4L.
600 1200 T.

IN SENATE

RESOLVED, That the following be the

REPORT of the

Supposing the wings of each T to give way, the battalions which penetrate there will find themselves between two columns hedged in with bayonets; the 10 battalions in reserve, which, according to this disposition, ought to join the right and the left of the infantry, should of course separate the two wings of the infantry, which are on the outside of the disposition in columns. Four battalions should remain in pursuit of them, and the two last take the line in flank, at the same time that it is attacked in head. The cavalry should charge the line which is in wall, with great vigour; and the second line should follow it very close, but in good order: the cavalry, or hussars, which are posted sidewise, will attack it in flank, and the dragoons must remain in their post, in order to keep back the enemy's second line.

Whatever dispositions are made in the drawing up of an army, they should always have some object. A general should foresee all that may be done by the enemy, whose disposition he should always suppose to be a good one, and to which he should oppose one at least as strong, and always better; if possible, he should particularly conceal from him the motions he intends making, or disguise them from him in such a manner, that he shall not have time to oppose them, at least not readily enough: neither should a general be so near as to give the enemy an opportunity of discovering and profiting by the method he intends following.

The disposition of an army in wall is good; but in general, only so with respect to infantry, because that body acting by itself requires but very little ground to retreat, or present itself to the enemy, or to make a motion to the right or to the left. But this same disposition is defective, and even hurtful for cavalry, unless there is a moral certainty of its getting the better: but as, with regard to war, a moral certainty would be a real presumption, this disposition of cavalry in wall would be dangerous, because it may be broke. If that which is opposed to it marches up to it resolutely without confusion, and without being afraid of that mass of cavalry, and charges it the first, sword in hand, how can it retire in order if it is broke, being as much straitened in its retreat as in its disposition? All the squadrons filling up the ground, it will neither be able to make any evolution, or to act; and if it retreats through the large intervals of the second line, it will carry it away with it in its flight: were there even six lines behind it, they would all be carried away, the second by the first, the third by the second, and so on with the others.

It is true that it may give the first charge, and consequently make those squadrons which have intervals give way; but as these last have more ground to act on, they can retreat with greater ease than those who have none, by passing through the intervals of the second line, which is not to be done by a line that hath no interval. They can rally in the rear, while the second will charge the line that is without interval, and which is already disunited by its first attack; even when these two lines are beaten, they can retire with greater ease, each squadron having ground enough to act upon. They will never be so much disordered as the line which has no interval, which cannot escape being cut in pieces if broke, or which can only find its safety in flight; whereas, those that have intervals can retire

one after another, and in a soldier-like manner, sustaining each other.

Besides, in order to prevent the impetuosity of this cavalry in wall, it appears that nothing is to be done but to post hussars, if there is not a sufficiency of horse, behind the squadrons of the first line, who, when the two armies begin to move forward in order to charge, will place themselves on the right and the left sidewise, 100 paces distant from the first lines of cavalry: by this position, they will be able to take the enemy's line in flank, whenever it comes to attack the cavalry. If a part of this line perceiving this motion, divides into two, one part to attack the line that has intervals, and the other the hussars, it is so much strength lost; consequently, the line with proper intervals has fewer troops to fight, and may expect to break them by giving the first charge. If the hussars should be beat, it is of no great consequence, the defeat of those troops never deciding the success of the battle: it is the body of the army the enemy must break, and not two regiments of hussars, which retreat with great ease from before cavalry, and rally and return to the attack as readily as they retired. But if, instead of hussars, cavalry can be posted there, the enemy's line, which is divided into two, will find itself obliged to fight upon equal terms: the certainty of success depends upon the quickness with which the enemy is attacked; and the more so, as he will be obliged to make a motion in the presence of troops already posted and ready to charge. If this line without intervals advances, without showing any attention to the hussars, in order to charge the cavalry, the hussars, at least a great part of them, ought to fall upon the flanks; and the dragoons, which are in the rear of them in reserve, should take their place, to keep back the enemy's second line, and to prevent the hussars from being taken in the rear.

These two dispositions are ideal. A general seldom chooses to fight upon a spot where the wings are void of support; and prevents the enemy, as much as possible, from getting possession of an advantageous post, or at least does not attack him when he cannot prevent him doing it, especially if the ground which he occupies is every where exposed: there are, nevertheless, circumstances where a general is obliged to fight, although not in a post strong by situation. By the two dispositions just now described, the order which would be most proper to be preserved for covering the wings, which may be exposed by the situation of the ground, has been endeavoured to be shown; it has been seen of what consequence it is for a general to know, and to secure all the heights, morasses, hollows, and every obstacle he may meet with. On occasions so important, a general should take the same precautions that he would use under the cannon of a place, if he found heights that overlooked the works; in which case he would not fail of constructing others more advanced, to prevent the enemy from getting there, and retarding their approaches.

If the duke of Savoy, at the battle of Marfalle, gained in 1698 by the French army, commanded by M. de Catinat, had been possessed of the heights of Piosca, the two wings of that prince's army would have been supported; instead of which, his left wing was exposed. M. de Catinat, profiting from this fault,

extended his right to the foot of those heights, of which he possessed himself, and out-stretched the enemy's left : it was from these heights that the disorder in the duke of Savoy's army commenced ; it soon communicated to the whole front, and got possession of the whole army : so true it is, that the most trifling object, being neglected, changes the order of things ; that the least fault becomes essential ; that confidence in the number and in the courage of the troops is often dangerous ; and that having a contemptible opinion of an enemy is always fatal. The enemy, although inferior in troops, will soon attain a degree of superiority, if he has the advantage of ground.

In a battle it is impossible that the two armies should be equally well posted. That which is attacked, by taking a good position, and there making up by the assistance of art what is wanting in situation, may maintain itself it that post, and defend itself in it obstinately. On the contrary, the army that would attack, can, in approaching to the enemy, profit only of the advantage the country offers him ; and by the disposition of his troops, make up for the badness of the ground, and attack the enemy although advantageously posted : it is on such an occasion, that a general's capacity opens itself, and shows the great man ; whether by properly attacking the enemy in the weakest part, by employing his whole front, and by preventing him from sending assistance to the troops attacked with force and vigour ; whether by posting his own troops after such a manner, that notwithstanding their facing the enemy in a disadvantageous post, they can be neither surrounded or flanked. It should always be contrived into a fault, when the enemy has time given him to post himself advantageously. It is necessary for a general to be beforehand with the enemy in possessing himself of the post which the enemy had resolved to take ; not in order to wait for him and receive battle in it, unless it should be impregnable ; but he should seize on it, to prevent the enemy's taking it, and attack him either on his march, or in some situation less strong, which he can neither have perfectly examined, nor had time to fortify. [This must be understood in relation to offensive war ; for in defensive war, a general must carefully avoid fighting, and be contented with guarding his country, covering his towns and magazines, in taking such camps as are strongest by their situation, and in joining the assistance of art to nature.]

In offensive war, a general must act in such a manner, as to be beforehand with the enemy in all his designs, in his marches, in the posts he would take ; and suppose he hath had time to possess himself of a good situation, he must not have time given him to fortify himself in it, and to render it difficult to be forced.

But a general, whether acting on the offensive or the defensive, ought always to be watchful ; sleep is dangerous to him, with whom the safety of the army and the security of the state are entrusted. A dream sent by Jupiter to Agamemnon, in Homer, told him, that a general who presided at so many councils, who had such numbers under his command, and who was loaded with so many cares, should not sleep the night out.

Armies can engage in so many different positions, that it is impossible to particularise all of them. In the beginning of this section two armies have been pre-

sented in an open country, without any support to to their wing ; two others have afterwards been posted, one of which is upon a spot advantageously situated, its two wings covered ; the other hath only its right wing supported, and its left exposed. It has been endeavoured to give to that, whose left wing is unsupported, the greatest strength in its whole front that is possible, and by the disposition of the left wing it is both strong and secure ; but there are such a variety of spots where two armies may meet, that it will suffice to know in general the advantages they may derive from their situation.

A general may cut off the communication of any assistance the enemy would send to the troops which are vigorously and briskly attacked, by employing his whole front with a few troops ; but they must be supported, and not exposed to the danger of being cut off.

It is always a great fault to give battle on a disadvantageous spot ; and if circumstances do sometimes require fighting, the general should, as much as possible, contrive that the cavalry be not exposed to the cannon ; but should at the same time take care that it doth not quit the support which it gives to the infantry, which cannot be done unless it is covered by a bank, or by hedges, and which, nevertheless, should not prevent its marching on the first order.

A general should, as much as possible, prevent the enemy from getting possession of any post, however trifling, and should prevent also his overlooking him. But if the enemy should get the possession of such a post, he should at least prevent him from fortifying himself in it ; he may have spies on whom he can depend, to penetrate into his designs ; he should also have advanced detachments, who, by incessantly observing the enemy, may give intelligence of all his motions.

An officer's negligence is more dangerous than his inability. The desire of acquiring honour gives activity ; but it is the love of his profession that gives him the penetration necessary for searching into the most secret designs.

DISP. III. This third disposition is very different from the two which precede it. The enemy's army is supposed to be advantageously posted ; it hath a hollow on its right, through which run the waters of an impassable morass, forming a rivulet. Its left is supported by a large town, crossed by a rivulet. In the centre is an height, capable of containing 12 battalions ; in the front of it is a plain of 700 or 800 toises, which extends from its left to the cavalry on its right. Opposite to this cavalry the plain grows narrower, by reason of an height which reaches to the rivulet, and which the cavalry could not occupy, because the enemy hath taken possession of it during the night. The town is entrenched, and filled with infantry and artillery ; 16 battalions in two lines are posted next the town, in order to sustain the troops that are in it. Behind the town there are three bridges upon the rivulet : in the front of the town, on the other side of the rivulet, are posted four battalions and five pieces of cannon, in order to flank the troops intending to attack the town : these four battalions are sustained by eight squadrons of dragoons. The centre of the army consists of 20 battalions in the first line, and as many in the second ; eight of which are
next

next to the morafs, fustained by fix fquadrons of dragoons; 12 fquadrons in the firft line, and 12 in the fecond. The cavalry on the right confifts of 11 fquadrons in the firft line, and 11 in the fecond. Thirty fquadrons of huffars, diftributed half on the right, and half on the left, and the whole front of the army lined with artillery.

The army A, which was encamped a quarter of a league from the height by which it is feparated from the enemy, began its march at dark; it halted at the foot of the height, and fent fome detachments of infantry to take poffeffion of the fummit of it. The army I, made the above-mentioned difpofitions, becaufe the army A was too near to be able to avoid a battle. The army I, is compofed of 78 battalions and 90 fquadrons: thefe two armies are nearly of equal ftrength.

The left of the army A, hath a fine plain before it, extending from the morafs to that part where the height commences. In that place are pofted eight battalions, in two columns of four battalions each, next the morafs, with 10 pieces of cannon between the two columns: there are 14 battalions in the firft line, and 13 in the fecond; four battalions towards the height, and next the cavalry. Sixteen battalions occupy the height as far as the fmall wood; four battalions occupy the other fide of the wood, and 32 battalions upon two lines very clofe together; 12 battalions behind the height next the rivulet; 12 fquadrons of horfe, and 20 of huffars, who have orders to pafs three bridges, thrown over the rivulet, and attack the town with three columns of four battalions each, fustained by the 12 fquadrons of horfe, and the 20 of dragoons. In the rear of the cavalry upon the left, are pofted 16 fquadrons of dragoons at a little diftance, with intervals; fo that, if the enemy fhould attack this left and beat it, the cavalry may eafily retire through the intervals of the dragoons, to give them the greater facility of ading, and turn their defeat into an almoft certain victory. Fifteen fquadrons of horfe are pofted behind the height, with their right toward the height, and their left toward the camp, in order to take the enemy in flank, whilft he is employed in purfuing the cavalry of the left, which he has beaten. The chief object of the attack fhould be the town, although the moft difficult. If it is forced, the enemy will be beat without refource: becaufe the infantry who has driven him from that poft, will attack him in the rear; at the fame time that the infantry which remained on the height will come down from it, and join, either to attack, or at leaft to employ the enemy upon the height, and by that attack prevent him from fending affiftance to the troops already driven from the town and put to flight: the cavalry upon the left will advance at the fame time to fupport the infantry, and, if neceffary, to charge the enemy's cavalry.

The 32 battalions which are upon the height in two lines, will be divided into fix columns, of which four of fix battalions will be employed in attacking the town, the laft battalion of every column excepted; which muft remain at the entrance of the wood, with four columns of four battalions upon the left, in order to fuftain the infantry attacking the town, and to keep back the enemy's cavalry upon the left. They will defend from the height under the protection of the

wood by which it is covered, and which ends at about 400 toifes from the town. Thefe troops will be followed by artillery, which muft be pofted between the columns; they muft halt on leaving the wood, and will begin by making a continual fire of cannon upon the town and the cavalry: during this fire of the artillery, the 12 battalions on the other fide of the rivulet ought to attack the four battalions and the eight fquadrons of dragoons belonging to the enemy; and when they have forced them to give way, they will amufe them by a conflant fire of mufquetry. When the artillery fhall have played long enough to have broken down the enemy's entrenchments, and destroyed the order of the troops, the four columns, formed of 20 battalions, will march up, and with their bayonets endeavour to penetrate at fome part; the 12 battalions on the other fide of the rivulet will charge at the fame time; the two columns of four battalions each, as well as the four laft battalions belonging to the columns which attack the town, will remain at the entrance of the wood with the artillery, in order to keep back the enemy's infantry and cavalry which was next the town. If any one of the columns can penetrate as far as the bridge that is in the town, it will take poffeffion of it, as well as of the market-place; the others following it will take poffeffion of the hedges and gardens. One column only will be fufficient to fecure the banks of the rivulet, and take poffeffion of the bridges. As foon as the bridges are free from the enemy, the 12 fquadrons of horfe and the 20 of huffars will pafs and attack every thing they find to oppofe them; then the left ought to advance: the battalions which have remained upon the heights fhould come down from them, and all together attack the front of the army, whofe left wing is already broken and taken in flank.

But if the enemy, after having examined the difpofition of the army A, imagining that the principal attack will be directed againft the town, inftead of remaining in his firft difpofition, changes it entirely, and caufes a part of his fecond line of infantry to march to the town; and if he ftrengthens his right by the cavalry of the left, (a fpot more favourable for cavalry than infantry), the attack of the town will then become impracticable, becaufe of the great fuperiority of the troops defending it; therefore, it would be ufelefs to preftit in it; but his right fhould be vigorously and brifkly attacked. It is true, that it is reinforced by the cavalry from the left; but as the ground between the height and the eight battalions which are next the morafs, can contain but 12 fquadrons, thofe which the enemy hath drawn from the left can only be pofted behind the height or in the third line; if they are behind the height, nothing can prevent their being attacked: but fuppofing the firft line broken, it fhould not be too warmly purfued, for fear of feparating, and being taken in flank by the cavalry behind the height. The 16 fquadrons of dragoons which are behind, ought to remain in that fituation: the 15 fquadrons of horfe, which are with their right to the height, and their left to the old camp, ought to take the place of thofe who have attacked the enemy; and then the 20 battalions which are upon the height, will come down into the plain and attack the enemy's infantry, at the fame time that the 15 fquadrons of cavalry and the 16 of dragoons attack the cavalry

cavalry which is posted behind the height. If they succeed in beating it, or whether the enemy send assistance or not, if he sends assistance, he will weaken his left, and then the 44 battalions, who till this time have remained inactive, may come down from the height and attack the town, not so much with a design of forcing it, as to oblige the enemy not to take any troops from it; if no assistance is sent to the right wing, it will be undoubtedly beaten, being attacked by forces so greatly superior to it: the whole of the cavalry being thus put to flight, the most prudent part the enemy can take is, to endeavour to pass the rivulet by the three bridges behind the town, and by so doing secure himself from farther insult: if the enemy does this, the 12 battalions, the 12 squadrons of horse, and the 20 of dragoons, will retire by the same road they marched up, and they will be in security as soon as they are in the wood: besides, a beaten army is seldom to be feared; therefore, they may retire unmolested, and in order.

But if it happens that the enemy, without changing his position, is not to be forced in any of these attacks, the general had better retire to the height, where there will be no danger of the enemy's endeavouring to attack him: but if he should attempt the attack of the left wing of the army A, it must be reinforced by all the cavalry that can be employed without causing confusion, and two brigades of infantry should be joined to the two which are next the morais. See Plate CCXCVI.

DISP. IV. The fourth disposition is supposed in a country mixed with thickets and plains. The enemy's army hath its right to some mountains, and its left to a river; in about a third part of the length of his front, there is a village a little behind its right. His disposition is, four battalions and six pieces of cannon upon an height which overlooks the plain, to which is also added the cavalry of the right. Behind are two passes entrenched and guarded by four battalions; upon the heights of these passes there are four more, to prevent the enemy penetrating at the flank. There are eight squadrons in the first line, four battalions posted at the village, and 12 in it with cannon: 16 battalions on the left of the village, 14 squadrons and four battalions next the river. The second line consists of 11 squadrons upon the right, eight battalions behind the village, in order to carry timely assistance to it; 12 battalions in the rear of the 16 of the first line; 15 squadrons and four battalions to the river. The reserve consists of 18 squadrons of dragoons next the mountains, (in order to dismount and be within reach of assisting the battalions guarding the passes), and of 24 squadrons of hussars on the left next the river. An island is supposed a little in the front of the first line: in this island is placed two battalions and six pieces of cannon. A stone-bridge is also supposed between the two lines, behind which is posted two battalions, to support those in the island, and to facilitate their retreat. It seems impossible to attack an army thus situated; all the troops are a mutual support to each other: the flanks are secured and well guarded; artillery is planted along the whole front; and the passes are entrenched, and troops posted in them.

In the front of the enemy's army is a large plain, which runs from the mountains as far as the river;

but the largeness of it is broke into by some thickets, where nevertheless cavalry may act: in order to attack this army, thus advantageously posted, a disposition must be made, entirely different from that which it is in. If the village, which is entrenched and well furnished with troops and artillery, is attacked, the forcing it will be doubtful: but supposing it should be forced, it will be without losing a great number of men; which should be avoided, because it is the duty of a general to spare the blood of his soldiers as much as possible, and even, if practicable, to employ but few of his troops against a greater number of the enemy's. If the passes only are attacked in order to take the enemy in flank, it is very certain he can send assistance to it without weakening his front, having it in his power to cause the eight battalions in reserve behind the village, to march there, and to cause the 18 squadrons of dragoons to dismount. If only the left wing next the river is attacked, it is true that attack is more practicable, there being no obstacle or entrenchment to prevent coming up with the enemy; but still there is but one wing beaten; and that, by falling back upon the troops in the village, can retreat by the mountains of which the enemy is master. There is great reason to imagine it will be beat; but the general must endeavour to reap as much profit from that victory as he can: it is therefore thought, that, not to lose the fruit of it, the enemy should be attacked on the left wing, from the centre to within about 200 toises of the river, at the same time that the entrenched passes are attacked. During these two attacks, a brisk cannonade should be kept up upon the village, the infantry and cavalry upon the right, the infantry that is posted in the island, and that which is next the river: by these two attacks the enemy's front and right wing will be equally annoyed; he will not know where to send assistance, and in that state of uncertainty may probably send it to a part where the danger is not so pressing. But suppose he should act in the most proper and prudent manner, as it should always be imagined he will, the assistance which he will send to that part, cannot be effected without furnishing or weakening some other: if he strengthens the passes and the heights of the eight battalions behind the village, they perhaps will not be forced; but he will scarcely venture to take any troops from the village, in order to send them to the assistance of the front that is attacked. But if he should furnish the village, it must then be attacked, and that vigorously; which may be the easier done, as it hath been for some time cannonaded, and consequently the earth hath been tumbled down, and openings made, at least large enough for the infantry to enter it: this attack will not at all prevent that at the front from going on.

In order to execute the attack upon the enemy's army, it is imagined the troops ought to be distributed after the following manner: all the infantry should be placed in the first line, excepting that of the reserve, which should consist of 20 battalions; the second line should consist of the cavalry; and the third should be formed of the dragoons and hussars. The 20 battalions on the left, forming five brigades, should remain in order of battle at the coming out of the thickets, with artillery distributed between the intervals of each brigade; the 28 battalions, after making seven brigades

 Feet

A. Bell & Co. Eng.

grades as soon as they come out of the thickets, will form in column: then the 24 squadrons which are in the rear of the infantry formed in column, will post themselves, four squadrons in the intervals of each brigade. The brigade supporting the right flank will advance on the side of the river: and then the seven columns and the 24 squadrons will march up to the enemy and attack him with their bayonets, without losing time in firing. As soon as the columns have broken or staggered the enemy's first line, the cavalry will fall furiously upon them, sword in hand; a part of the dragoons and hussars should follow, in order to be within distance of sustaining the troops who have attacked, or to join themselves to the cavalry who have broken in among the enemy: it should be observed, that as soon as the hussars are engaged and pursuing the enemy, the cavalry should rally in order to sustain them, or to flank the infantry which may still make resistance. The brigade of infantry which supported the right, followed by the seven squadrons, should attack the four battalions on the left of the first line, and the seven squadrons will take them in flank; which they can with the greater ease effect, as the cavalry hath been put to flight. The seventh column should, with four squadrons, attack the four battalions of the second line, at the same time that this attack is executed from the front as far as the river; 16 battalions of the 20 in reserve, should attack the passes, and also the heights; the remaining four will march under cover of the mountains, sustained by a brigade of infantry and eight squadrons, in order to attack the cavalry on the right; thus of the whole front of the enemy's army, there will remain only the village that hath not been attacked, unless there hath been such a number of troops drawn from it, as to render the carrying of it not difficult. It is to be supposed that one of these attacks will succeed; that made by the columns sooner than the rest: the disposition of columns intermixed with cavalry is very formidable, because each body is supported without confusion: besides, it is to be supposed that a column four battalions in depth, and from 18 to 20 men in front, ought to break through a line that is only four deep, and which being once penetrated, the cavalry will find no difficulty in breaking through it. See Plate CCXC VII.

The movement of the infantry to form itself in column, and the evolutions of the cavalry to fill up the intervals of each column, ought to be performed with great quickness, and near enough to the enemy to surprise him, but not at such a distance as to give him time to remedy it.

The nature of the ground, which is continually changing, cannot be followed through all its various shapes; the author hath therefore endeavoured to form his dispositions in those situations which most ordinarily occur, in order that these general dispositions may be assailable to the ideas in more particular and critical situations. Mountainous countries have not been mentioned, because it is very rare that they present an opportunity of coming to a general action: the affairs which happen among them are generally with regard to some post, which can never decide the fate of an army, however brisk they may be. The four dispositions now mentioned, are ideal; and although the pro-

priety of them may be defended, it would be very imprudent to answer for their success; because with regard to the business of the war, the whole depends upon circumstances, and the least accident often renders a disposition, seemingly the best, the most prejudicial that can be taken. A motion of the enemy's troops ill conducted by their commanders, too much sloth or too much eagerness in the execution of orders, an accidental word falling from the mouth either of an officer or a soldier, and which is always increased when told again, may occasion the defeat of an army, however well disposed or advantageously situated. The epithet of "best" should be given to that general who commits the fewest faults; for there is no man who can flatter himself with having committed none: it is impossible for a general to see every thing himself, or to remedy any unforeseen accident that may happen, if he is not assisted by his general officers, who see things which it is impossible he can: they ought not only to be the means of putting his orders in execution; but even, in certain circumstances, they should prevent them, and make the same dispositions which the general ought to make, and would certainly order, was he in their situation.

EXPLANATION OF PLATES.

PLATE CCLXXXVIII. a, The army formed in order of battle, ready to march. b, The park of artillery, where the baggage belonging to the army, and their escorts, also are assembled. c, March of the cavalry, to form the column on the right. d, March of the cavalry, to form the column on the left. e, March of the infantry, to form in three columns. f, March of the artillery and baggage, to form in a column. g, Parties of hussars, covering the flanks of the army, and forming the rear-guards of the column, when the army hath passed. h, Bridges and fords, discovered by the advanced detachments, who have marked the route of the army. i, Bridges built by the same detachments. k, Front and rear-guards of the columns drawn from the troops of which the columns are formed. l, Parties of hussars, marching upon the flanks of the army. m, Parties of hussars marching at the head of the army, to scour the country through which the army is to pass, and also to examine the routes marked by the advanced detachments.

PLATE CCLXXXIX. A, The position of the army, before it begins the march. B, Parties of hussars forming the advanced-guard of the army. C, Parties of infantry of the advanced-guards of the columns. D, The infantry of the army forming the head of the columns. E, The artillery, and waggons belonging to the artillery. F, Battalions of artillery. G, The cavalry. H, The baggage of the army. I, The escort of the baggage. K, Parties of hussars. L, Parties of dragoons. M, The infantry of the reserve, forming the rear-guard of the army. N, Platoons of infantry marching upon the heights, to cover the flanks of the columns. O, Villages in front of the camp the army is to occupy, and of which the light infantry have taken possession. P, The artillery and baggage, with their escorts in the front of the camp.

of battle. B, The cavalry, which hath marched some paces in advance, in order to make room for the infantry. C, The infantry, which, by facing to the right, forms the column upon the right. D, The infantry, which, by facing to the left, forms the column upon the left. E, Bodies of infantry, which are to march at the head of the columns of cavalry. F, The park of artillery, where the baggage belonging to the army, and the efforts, also are assembled. G, The march of the infantry, forming in columns. H, The march of the cavalry, forming in column. I, The march of the artillery and baggage with their efforts, forming in column. K, The army in march. L, Hussars of the advanced-guard keeping the roads, marked out by the detachments sent on before. M, Infantry, forming the advanced-guard of the columns. N, Small parties of infantry, marching upon the flanks of the columns. O, Parties of hussars, marching upon the flanks of the army. P, Infantry of the reserve forming the rear-guard of the army.

PLATE CCXCII. A, The camp of the main body of the army. B, An advanced camp, composed of dragoons and hussars, in order to cover the right of the army, to guard the passes by which the enemy might make incursions upon the flanks and rear of the army, molest the convoys, and cut off the communications. C, Villages and bridges, guarded by the light infantry. D, Posts of dismounted dragoons in the front of their camp. E, Posts of dragoons on horseback, to secure the communication between their camp and that of the main body of the army. F, Bridges built, to keep up the communication between the grand and the advanced camp. G, Bridges and villages guarded by detachments of infantry. H, Grand guards of horse. I, Guards of infantry. K, Bridge, village, and mill, guarded by the infantry belonging to the army. L, Camp of dragoons and hussars covering the left of the army, and supporting the light infantry. M, Villages and bridges guarded by the light infantry. N, Posts of dismounted dragoons in the front and on the flanks of their camp. O, Posts of dragoons on horseback. P, Posts and detachments of hussars, to patrolle in the front and upon the flanks of the army, and their camp.

PLATE CCXCIII. A, The army encamped behind its entrenchments. B, The camp of the troops of the reserve. C, Camp of the dragoons, to secure the rear of the army. D, Camp of hussars, to cover the ground upon the right of the army. E, Villages

and redoubts guarded by the light infantry, to secure the camp of the hussars. F, Bridges built to secure the communication of the army with the ground upon the right, and to favour the retreat of the troops posted on the opposite side. G, Brigades of artillery distributed upon the flanks, and along the whole front of the army. H, The park of artillery. I, A bridge entrenched, to secure the communication between the army and the ground upon the left. K, Villages and farm-houses, guarded by detachments of hussars and light infantry, to patrolle in the front of the army.

PLATE CCXCIII. fig. 1. A, The camp of the army, divided into three parts, for the defence of the river. B, The camp of the light horse, light infantry, and dragoons upon the wings of the army. C, Castle and village, guarded by light infantry. D, A town occupied by the infantry belonging to the army. E, Bridge broken down. F, Islands occupied by infantry. G, Posts of infantry distributed along the side of the river. H, Batteries established along the side of the river. I, Posts of cavalry, to keep up the communication between the camps. K, Bridges constructed to preserve the communication of the islands. L, Bridges constructed for the communication of the camps.

PLATE CCXCIII. fig. 2. A, Bridges of boats. B, Redoubts which cover the bridges. C, A battery, under cover of which the infantry work at the construction of the redoubts. D, A battery to prevent the enemy from annoying the army on its march. E, The march of the army. F, The artillery distributed among the brigades of infantry. G, Infantry, forming in columns to open on the opposite side through the intervals of the redoubts. H, March of the columns into the front of the redoubts, who halt in order to give time for a part of the cavalry to form upon its flanks. I, A battery erected to facilitate the forming of the cavalry. K, Cavalry, which, in gaining the opposite shore, forms in order of battle, and posts itself upon the flanks of the infantry. L, Eight battalions in column upon the right wing of the army, to go and examine the village, and attack the enemy in it, in case he should be possessed of it. M, Hussars and dragoons, who have taken possession of the height which is on the left wing of the army. N, A brigade of infantry posted next the height, covering the left wing of the cavalry. O, The disposition of the army marching up to the enemy.

PART III. Of the PETITE GUERRE.

THE *Petite Guerre* consists in the manœuvres of the Partisan in secret marches, occupying, defending, or attacking posts, reconnoitring countries or the enemy, placing of ambuscades, &c.

SECT. I. *Of the Qualifications of a Partisan, and the Nature of his Corps.*

THEY generally call every officer a partisan who is destined to go at the head of a detachment, whether draughted from the body of the army, or of a party which he belongs to, and for that reason has no other name than that of a partisan.

Of all military employments, there is none which require more extraordinary qualities than that of the partisan.

A good partisan ought to have an imagination fertile in projects, schemes, and resources; a penetrating spirit, capable of combining the whole circumstances of an action; a heart intrepid against every appearance of danger; a steady countenance, always assured, and which no signs of disquiet can alter; a happy memory, that can call every one by his name; a disposition alert, robust, and indefatigable, to carry him through every thing, and give a soul to the whole; a piercing rapid

eye,

eye, which instantly catches faults or advantages, obstacles and dangers of situation, of country, and every object as it passes; his sentiments such, as to fix the respect, confidence, and attachment of the whole corps. Without these dispositions, it is impossible to succeed.

A partisan ought to understand Latin, German, and French, to converse with all nations. He ought to have a perfect knowledge of the service, especially light troops, without being ignorant of the enemy's. He should have the exactest map of the theatre of the war, examine it well, and become perfect master of it. It would be very advantageous to have some good geographers under his command, capable of drawing plans, routes of armies, situation of camps, and wherever they may have occasion to reconnoitre.

He ought to spare nothing to be assured by his spies of the march, force, designs, and position of the enemy.

As chief, he owes the example of an irreproachable conduct to his corps, circumspect in his cares like the affection of a parent, by which he will inspire respect, love, zeal, and vigilance, and gain the hearts of the whole to his service. It is extremely dangerous for such an officer to contract the least attachment to women, wine, or riches. The first makes him neglect his duty, and frequently occasions the most ruinous treacheries: the second leads to dangerous indiscretions, and is sure to draw down contempt: the third leads to guilt, and destroys all sentiments of honour. The partisan must be content without the delicacies of the table, as he may be often exposed to want provision; his bed the same with the mens, a cloak and straw, never stripping but to change linen. Nothing animates soldiers so much as the presence and vigilance of a commanding officer sharing with them the fatigues of the service: the officers follow his example; the men are assured, encouraged, and content.

To form a Corps capable of carrying on the *Petite Guerre* to advantage, prudence requires that it should consist of 1000 men at least; without which a partisan cannot expect to support the fatigues of a campaign, and seize the most important occasions that every where offer, and which a too great inferiority must make him forego.

It is no less important that this corps should be composed of infantry and cavalry; and as it is inconceivable that the cavalry ought to be the most active in carrying on the *Petite Guerre*, it were to be wished that they were likewise the strongest, so as to have 600 cavalry and 400 infantry in a corps of 1000 men, making four companies of infantry and 12 troops of cavalry.

Each company of infantry to consist of one captain, one first and two second lieutenants, four serjeants, and 96 men, including four corporals, four lance-corporals, and two drummers. Each troop of cavalry to consist of one captain, one first and one second lieutenant, a quarter-master, two serjeants, and 48 horse-men, including four corporals, a trumpeter and farrier.

The commanding officer should have the naming of the officers of this corps, or at least have liberty to reject such as he is convinced are not qualified for such service, as every officer who may be ambitious to serve in the corps, though possessed of great military merit, may not have the talents requisite for the duties of the partisan.

To support the honour of this corps upon a solid

and respectable footing, the strictest subordination must extend from the chief to all the officers, and the most rigid discipline inspire vigilance, patience, bravery, and love of glory to the whole corps.

As to the other corps of partisans formed of one or more detachments, drawn from the different regiments of the army, and composed with a view to some particular expedition, their strength and quality is regulated by the circumstances of the affair they undertake, and are more or less numerous according to the exigency of the projected scheme. It is of the utmost importance for the officer that commands, to have the choosing his men and officers whom he knows to be fittest for his enterprise, and thereby preventing many difficulties, contradictions, and dangers, which jealousy and distrust always occasion among strangers.

No recruit for the corps of a partisan, either cavalry or infantry, should exceed 30 years of age; but the younger they are, if they can carry arms, so much the better for such a service, to which youth are particularly inclined, and recruits may be met with every where; but when the necessities of war do not oblige officers to accept of indifferent men, they cannot serve the corps more essentially than in the choosing good recruits. We learn from Vegetius, that the best service is to be expected from men brought up to severe labour, and exposed to the injuries of the weather; men brought up in ease and plenty cannot endure fatigue and want, and they who have tasted fewest of the sweets of life are the least subject to the fear of death. In the choice of recruits for the cavalry, it were not unworthy the attention of officers to prefer men that are lovers of horses, and to recruit chiefly in those countries where such are mostly to be expected.

As for arms, the firelock and bayonet is sufficient for a foot soldier; but in the corps of the partisan, barrels of 36 inches, with a long bayonet, but to have the caliber the same with the rest of the army, which, for the sake of having ammunition made up to suit the whole, ought to be invariably the same; and for the more convenient method of carrying their ammunition, the German manner, of having their cartridges placed horizontal, and covered with wax cloth, is preferable to our wooden blocks. A helmet likewise is preferable to our hats, as the sword is almost the only thing to be dreaded from the enemy's cavalry. Four spades, and four pick-axes should be given to each company of infantry.

The present manner of equipping the light dragoons is so perfect, it is unnecessary to say any thing on that head; but no white horse, stone-horse, or mare, should be suffered in the corps of the partisan, as the least neighing or perceivable colour may make enterprises fail. No horse should be mounted for service till six years old. The size of the light dragoons is very proper for the partisan; and while they have firm ground to act upon, and plenty of forage, none can excel them; but when they come among morasses, and feel the severity of want, perhaps the Hungarian Hussars may be found more equal to the duty: possibly, therefore, in forming the corps of the partisan, 200 horse, such as are bred in the mountains of Wales or Scotland, mounted by the lightest men, might be found of good service.

The principal attention of an officer of cavalry should be, to see that the men feed and dress their horses well,

Hay, straw, and oats, are their common food: too much hay is not good; but when they find wheat-straw newly threshed, they may give them more of it, as it is excellent nourishment. During the whole campaign they should have dry food only, as green weakens them.

When the exigency of the service requires the horses to be kept saddled day and night, every horseman should seize some moment to turn the saddle-cloth, which greatly comforts a horse, keeps him at ease, and less apt to gall; and care should be taken to keep the cloth soft, and clean from sweat and dust.

SECT. II. *Of Posts, &c. and the different Works with which they may be fortified.*

Posts are generally such places as bodies of troops can fix in when detached from the army, to cover and secure the frontiers; and upon the vigilance and resistance of the parties that are detached there, depends the safety of the army. Whatever the abilities of a general may be, it is scarce possible that he can have an eye to every detail that contributes to their defence; it is sufficient if he knows that the guards are properly placed, and the line that they make properly established. It is then the business of the particular officers who command them, to make the best disposition for a vigorous defence, and answering the views of the general.

An officer who is detached to a post, is either to relieve a party, or take possession for the first time. In the first case, if the guard which he relieves happens to be intrenched, as soon as he arrives at the post, and has taken his instructions from the officer who commands, he should prepare himself for his defence, as shall be mentioned in that article. In the second, if an officer who is detached is to intrench himself, he must examine if the place is advantageous for the execution of his projects, the defence of his people, and the securing a retreat.

He must consult, 1st, Whether the situation be convenient for sending parties to discover the enemy; whether to give intelligence of their situation and march, or to disturb and surprise them. 2^d, If it has some natural defence on its front or flanks, such as a river, rivulet, morass, or small wood that can be easily penetrated. 3^d, If he can preserve his communication with the army, and if there are some covered places to favour his retreat. 4th, If he can discover all the approaches; because if the enemy can come within a small distance of the post without being seen, he will place himself under cover there, and rest while the besieged are obliged to remain continually under arms, and will watch the moment for making an attack. If then he finds hollow roads, clumps of wood, or any place where the enemy can secure himself in the neighbourhood of his post, he must fill them up, or guard them with detachments of six or seven men. 5th, He must take care not to be commanded by any neighbouring heights, or must prevent the enemy from profiting by that advantage; because if they can take his soldiers in the rear, it will be impossible for them to defend themselves. You will see afterwards how to ward off this inconvenience, when you cannot prevent being exposed to these heights. 6th, The extent of the work must be proportioned to the number of men

that are to defend it. Good sense and numberless examples prove, that too large intrenchments (such as are commonly constructed) can only be defended by considerable bodies. Excesses of this kind are extremely reprehensible; and it were much more eligible to give in to the opposite, by making them smaller. 7th, He should take care to have all the parts of his intrenchment nearly of an equal strength, so as to be able to make an equal resistance every where; and lastly, he will take care to fulfil exactly the intention of the general in posting a guard in that place.

There are some places so advantageously posted by nature, that though they are not fortified, they may in a short time, and with little charge, be made so strong, that it will require as much art to besiege them as many others that are perfect fortifications; such as islands, peninsulas, and places seated on eminences of difficult access, or in morasses.

If the post is in a level country, or upon a height that may be surrounded, as happens almost always to small detachments, they should construct a redoubt or small square fort, composed of a parapet with its banquette access, and places.

If the post is in a level country, or upon a height that may be surrounded, as happens almost always to small detachments, they should construct a redoubt or small square fort, composed of a parapet with its banquette access, and places. The ground being chosen, you must trace a straight line AE, (fig. 1.) and raise the perpendicular BC, as directed in practical geometry; observing to give to each of these lines which mark the interior side of the parapet but two toises, or two and a half for 30 men, four toises for 50, and eight for 100; which will leave a space of two feet at least against the parapet for each man.

Having traced the two first lines A, B, you must put the cord over the picket C of the perpendicular B, and with the same length trace the arch D, then put the cord over the picket E of the line A, and trace the arch F. The point where the arches intersect each other, is the point to end the lines EH and CG. These four lines mark the interior side of the parapet.

Then trace four other lines at the distance of two or three feet parallel to the first, as I, L, M, N, to mark the size of the banquette, which should be greater or less according to the number of soldiers you would place in a file. Then trace a third parallel square on the outside of the first, as O, P, Q, R, to mark the exterior side of the parapet; and to determine its thickness, which is usually eight or nine feet, or 18 if it is to resist cannon, which you should always be prepared to do.

Then trace a fourth and last square, ST VX, to determine the width of the ditch, which is the same or two feet more than the thickness of the parapet; leaving a picquet planted at all the angles, as likewise at the lines already traced, so as not to lose the points from whence the lines were drawn.

While you are employed with two or three men in tracing, five or six men should be ordered to cut down the trees that are in the neighbourhood of the post, not only to open the approaches, but to serve for constructing the intrenchments. The smallest branches serve to make fascines, which are a sort of faggots about six feet long, two feet thick, and of the same size all over, tied in the middle and at the two ends, to serve for supporting the earth, which would tumble down without that support. The middling branches
serve

serve to make pickets proper for mixing with the fascines, and fixing them in the ground, or one above another to raise the parapet. The trunks to which the large branches are left, serve to increase the strength of a post, as shall be mentioned afterwards.

Having traced all in the manner directed, fix a row of fascines upon the small square ILMN, to support the earth of the banquette; then fix a second row upon the square ABGH, to support the interior side of the parapet; then a third row on the third square OPOQ, to support the exterior side of the parapet. You should observe in the beginning to picket the fascines, to leave a passage of three feet PB, on the side least exposed to the enemy, to serve for an entry to the redoubt; but if this passage can be taken in a straight line, it should be made like a mortoise, as you see at Y, fig. 2.

After having picketed the three rows of fascines as directed, you must dig the ditch AB, as in the profile fig. 3. a foot distant from the exterior side of the parapet. This distance or breadth is called *berme*, and serves to support the earth, or receive what falls from the parapet by the enemy's cannon. This *berme* is more or less according to the solidity of the earth; the earth to be thrown into the intervals C, D, E, marked for the parapet and banquette, taking care to make the men tread it well down, and observing to leave a *talus* or *slope* on the two sides of the ditch FG, more or less, according to the consistence of the earth, so that it may not tumble down. The slope F, which is on the side of the redoubt, is called, *the scarp*; and the opposite slope which is next the country, is called *the counter-scarp*. Care must be taken, in picketing the fascines with which the parapet is raised, to bring them nearer one another by degrees in raising it as at H, so as to leave the same slope on each side. The distance DE mark the banquette; the distance DC the thickness of the parapet at the bottom; the distance IL the thickness of the parapet at the top; MN the width of the ditch at bottom; AB the width of the ditch at top.

If the ground is level, the banquette of this work must be raised two feet; but in low places two banquettes are necessary, the one above the other like steps: but if this banquette is raised on account of some neighbouring heights from whence you may be taken in the rear, the parapet must be raised to such a height, that the enemy's shot can no longer plunge down upon you. A slope must be left on the top of the parapet, as IL, so that the soldiers may see round the post, and fire easily towards the country at O.

Though the square form of a redoubt which we have given the method of constructing, is almost the only one used in the field, yet it has its faults, which ought to make it be rejected, at least for those posts which ought to defend the environs equally. Experience shows us that we ought never to depend on the oblique firing of musquetry, as the soldiers almost always fire right forwards, as at A, fig. 4. and often even without taking aim. This being the case, there are large spaces opposite to the angles of the redoubt at B that are not defended, and where we may say that the enemy remains in safety. The chevalier Clairac proposes an excellent method to prevent this inconvenience, by constructing the interior edge of the parapet, like the

edge of a saw, in form of small redans, to hold a man or two in each side, fig. 6. which by the cross fire takes the enemy on the two flanks, so that there are no approaches but what are defended; but the construction of this redoubt is too tedious and complex to be executed by small detachments.

The same author prefers constructing circular redoubts as at C, fig. 5. because all the points of the circumference being equally disposed, the soldier posts himself indifferently over all; and the exterior spaces D which are defended, varying every moment, the enemy is nowhere in safety.

The circular redoubt then is the most perfect that can be constructed; but where a road or the edge of a river is to be defended, the square, or long, or triangular redoubt is preferable, because they ought to oppose the faces of the intrenchment as parallel as possible to the places they are to fire at, observing always to round the angles.

To trace a circular redoubt, after fixing the central point of the post, let a picket be fixed in that point, fig. 5.

and draw from it as center the circle EE, with a length of cord in proportion to the number of the party, to mark the interior side of the parapet; then trace another within the first, at the distance already given, to mark the banquette; then trace a third FF, to mark the exterior edge of the parapet; then trace a fourth GG, to mark the width of the ditch; which being done, picket the fascines, and make them take the bend of the circle, finishing as in a square redoubt.

If an officer is posted with a detachment on a passage or before a bridge, in a defile, or opposite to a ford, he may make a parapet either bending or straight, with a banquette or ditch which should shut up the whole entry; or he may make a redan, which is a work with two faces, and in such a situation should be made with a re-entrant angle, (that is, the angle pointing from the enemy); taking care, when he is to guard a ford, to construct it so near the river that the enemy cannot have room to form after they have passed. A deep ditch may be dug opposite to the ford, into which they should let the water of the river pass; they may likewise make the banks steep; throw trees across, and scatter chausse-traps, which are instruments of iron with four spikes, made so as to have always one point erect.

The strength of a redoubt or any other work may be augmented by blocking up the passages that lead to it; in a mountainous country, by cutting large ditches perpendicularly down, across the roads; by placing carts above one another in the defiles, with some soldiers behind them; and by throwing, wherever it is necessary, large branches of trees half buried in the ground: taking care not to break the way by which you must retire, so as to prevent your making a retreat; but on the contrary to leave an easy passage made in form of a draw-bridge, or any other way defended by seven or eight soldiers.

If detached into a level country, very deep ditches should be dug in the avenues and approaches of the post; or deep pits covered over with small branches and a little earth over them; taking care to scatter the earth that is dug out all round, so that the enemy may not be able to discover whereabouts they are; and chausse-traps may likewise be scattered in the avenues

Plate

CCXCVIII.

and on the glacis. Lastly, they may plant pickets all round the post near to one another, inclining a little outwards, six feet out of the ground, and the point made sharp after being drove.

But the most formidable obstacle, and which is preferred by Monsieur Folard, is to shut up the defiles, to block up the roads, surrounding the post with felled trees, and sinking their trunks three or four feet deep in the earth, which must be dug on purpose, leaving a number of large branches on them, which must be sharpened at the ends, and the leaves taken away, and placed as near to one another as possible, so that the branches may mix, and taking care that they incline towards the enemy. Two or three rows may be made in this manner; but they should be at least two toises distant from each other, that the enemy may not burn them all at once, to approach the intrenchments. M. Saxe in his *Reveries* says, that redoubts are proportionably advantageous as they take less time in constructing, and are proper for numberless circumstances, where one often may serve to stop an army in a close country, hinder them from troubling you on a critical march, or to occupy a large space of country when you have but few troops.

Intrenchments are sometimes made with felled trees alone, when there is no design, or time is wanting to raise an intrenchment of earth. The trunks should be placed towards you, and very close upon one another, with the branches sharpened and pointing to the enemy. This makes a very formidable parapet, when rounded so as to prevent the enemy getting sight of your people. There is no need to mention large works, which require engineers to construct, and great bodies to defend them; but a redoubt, such as A, fig. 7. may be strengthened by filling the ditch with water, by turning a rivulet, or cutting a river or pond. If the ground is uneven, so that the water cannot be put equally in all parts of the ditch, dams should be left in digging at C; or little traverses of earth to form banks proper for keeping the water in the upper part of the ditch D, from whence it may be let run into the lower E. These banks should have but half a foot in thickness at the height D, which should be raised sharp; but a good deal more must be left below at E, by sloping the two sides pretty much. Dams likewise are made of planks or boards, as at F; but they must be strong, and supported by large stakes, so that the body of water above may not overturn them; and then they are reckoned preferable to those that are of earth.

Particular Explanation of Fig. 7. A, The ground within the redoubt. B, The bottom of the ditch. C, D, E, Dam of earth. F, Dam of planks, boards, or fascines. G, Upper part of the redoubt constructed of fascines, and the earth dug out of the ditch. H, The lower part of the redoubt dug in the earth. I, The berme or space left at the bottom of the parapet to support the earth. L, The entry of the redoubt. M, The inside of the parapet. N, The upper part of the parapet. O, The banquette. P, The glacis. Q, Rivulet from whence water may be let into the ditch of the redoubt.

But it is not only with the works already mentioned that an officer may fortify a post; there are likewise an infinity of ways to stop an enemy, to tire him, and

even to repulse him, which it is necessary that he should not be ignorant of.

All the schemes for opposing the enemy, of which we have given a detail, serve only to add to the exterior strength of posts; there are others which have some natural fortifications, such as churches, church-yards, mills, or farm-houses, &c. An officer who is sent to a post of this kind, which is detached from other buildings, ought to observe, before he begins to work, to make the inhabitants go out, and the magistrates of the nearest place to receive and lodge them. You should then intrench the house with a turning parapet, if you have people enough to defend it; but if you have only a few, you should make a breast-work of felled trees round the house, especially opposite to the angles, to prevent the enemy from undermining it. You must likewise take off the tiles and slates, lest the enemy get up by ladders and crush your people that are within. If the house is covered with thatch, it should be pulled off and burnt, as well as every thing combustible that can be found in the neighbourhood, lest the enemy make use of it against the house.

Though the house is surrounded with a parapet of felled trees, you should not fail to pierce the walls with loop-holes, about a foot from the ground, so as to discover the enemies legs, that they may not get footing on the outside. These loop-holes should be four inches wide, and three feet distant from one another; and a little ditch should be made a foot and a half from the wall within the house, to place the soldiers in who are to defend it. Other loop-holes should likewise be pierced seven or eight feet from the ground, opposite to the interstices of the lower ones, and of the same width, placing the soldiers that are to defend them upon tables, planks, or ladders; and taking care to pierce a greater number opposite to the avenues, before, and at the sides of the gate, and the angles of the house, because these are the places where the enemy usually makes his greatest efforts. If the house has an inner-court, the walls should be pierced which inclose it, so as to fire upon the enemy after he has made himself master of it.

If there are several gates, they should all be blocked up except one to be left for an entrance to the post, which should be made so as to admit but one man at a time.

If there are low windows which are not grated, they should be shut up with dung, planks, stones, earth or trees. If there are any out-houses, such as stables, cellars, &c. several trees should be buried up to the branches before them, to prevent the enemy from forming, if they are about to penetrate into the house; and one or two trees should be put three or four feet within the entry, to prevent the enemy from penetrating right forward.

If there is a broad staircase for going up to the first floor, it should be broke down, or blocked up with stones or casks filled with earth. If it is a winding stair, the wall should be pierced in different places with loop-holes, to fire upon the enemy that are already entered, keeping ladders for yourselves to get up to the first floor, which should have the boards pierced with a number of holes about four inches diameter, to fire down upon the enemy, observing to pierce them only where there are no trees below, but

Fig. 8.

to have a greater number over the door and other weak places which the enemy can force.

Loop-holes should be pierced breast-high in the wall of the first floor, with about ten inches opening, and opposite to the interstices of those immediately below. If there are not people enough to defend the windows of the first floor, they should be barricaded, to prevent the enemy from firing upon those within; and a large opening should be made in the pavement opposite to each window a little longer than the width of the window, which is to serve by way of ditch, into which you may tumble those who penetrate that way.

The same way may be done with the second and third floors, so that there may be an equal resistance over all; but instead of piercing loop-holes in the highest floor, the tiles and slates being taken away, the wall may be taken down to breast-high for the men to fire over, the stones kept to throw upon the enemy, and the rafters to throw upon the ladders which happen to be placed against the house. A post intrenched in this manner may resist a great while, and even tire out the besiegers if defended by resolute men.

Captain d'Enfernay of a French regiment, with a company of volunteers, in the campaign of 1748, took post in the church of Bevera, two miles from Ventimiglia. It is detached from other buildings, and he fortified it with a parapet and ditch full of water; but his intrenchment was commanded by some houses in the village, so that the enemy could fire down upon his party. He remedied this defect by covering the commanded part with a kind of blind made with rafters, leaning one end on the wall of the church, and the other upon posts raised a foot higher than the top of the parapet, which left room to fire through. This blind, covered with fascines and earth, prevented the enemy's fire from piercing, and did not prevent his firing upon them, so that they durst not attack him.

This example is mentioned to shew how to secure a post that is commanded by a height. When there is no redoubt or intrenchments of earth, the interior side of the parapet which is commanded should be raised, or a sort of penthouse should be made with rafters, placed perpendicularly against the inner side of the parapet, upon which planks or fascines are nailed, taking care to leave room between the bottom of the penthouse and the top of the parapet for the men to fire through.

If an officer has not time to oppose all the schemes which have been mentioned to the enemy, when the general wants to make a forage, and throws infantry into the house to form a line, he should immediately place a couple of trees across before the door, pierce the boards, shut the windows, and prepare for his defence; which gives time to the foragers to retire, and the supporting parties to advance.

SECT. III. *Of the manner of fortifying Villages.*

THE manner of intrenching which has been mentioned, is only for posts that are detached from any building; but if an officer has a village to defend, he may cut out a much harder piece of work for the enemy. When we speak of intrenching a village, it is meant only of such as have the houses collected, and sometimes surrounded with a wall. An officer de-

tached to a post of this nature, ought to go several times round it, and observe the adjacent houses before he begins to intrench, and cause loop-holes to be pierced in them: the entries of those that have passages leading to the country should be blocked up with trees; and if he has time, he should make a good parapet of felled trees, and intrench the entries of the streets.

An officer who would fortify a post of some extent, ought to make a kind of plan of the village, and the intrenchments which he intends, which will often furnish ideas of defence, which escape on viewing the country. A street is to be defended, like a ford or bridge, with a redan, described above, or with a simple parapet in a semicircle with a ditch; making loop-holes in the houses at the entrance, and deep ditches across the streets, with chausse-traps thrown into the bottom of them. The streets should be blocked up with trees, carts, and casks; you should likewise open several passages in the back parts of the houses, to keep up a communication with the different streets: but above all, if you have but few men, the middle of every open place or square must be filled with felled trees, to prevent the enemy from forming if he penetrates.

As cannon or fire are most to be dreaded in the defence of a village, an officer ought to break up the roads by which cannon can pass, which is an easy matter in a mountainous country; but if the village happens to be in a plain, large ditches should be cut across the avenues, at every little interval placing trees across that take up the whole breadth. If there is time, the joists of the houses should be propped up with trunks of trees, or large pieces of wood put up like bricklayers' hories, to prevent their tumbling down and crushing the besieged. The best security against fire, is to burn all the materials that an enemy can make use of for that purpose; but if there is a quantity of wood, straw, or hay, the general should be asked whether he chooses to have it burnt, or carried off to supply the army.

Another essential thing for an officer to attend to who is detached to a village, is to secure his retreat in case he is forced at the entry of the street, or in his first intrenchments; he should therefore choose a church or large house separate from the rest, after having dislodged the inhabitants. When soldiers who defend a post know that they have a place to retreat to, they do not think of surrendering while they see themselves in a state of obtaining an honourable capitulation. But if the houses of a village are scattered, and there are gardens or courts in the centre, they must be content with intrenching a single house, church, or churchyard, where they may be covered with an intrenchment of earth, and employ all the schemes already given in the preceding section.

If the works with which posts, especially villages, are fortified, were to be executed by the soldiers of the detachments, who ought never to be fatigued, it would be too laborious and tedious; therefore an officer should cause a number of peasants, by the appointment of the magistrate, to work alone, or jointly with a third of the party, while two thirds remain under arms to prevent surprises. The soldiers and peasants should

be

be relieved every three hours by fresh men, taking care that they have no concealed arms, and work without interruption until the work is completed.

SECT. IV. *Of going on Detachments and secret Marches.*

DETACHMENTS are particular bodies of soldiers detached from a greater body, to guard a post, or to go on an expedition.

When an officer is ordered on a detachment, he should provide himself with a cord regularly divided, in case he has occasion to entrench; and be at the parade by times, to get information from the brigade-major, whether he is destined to relieve a detachment, or to occupy a post for the first time. If to relieve a party, he is only to know where the guide is who is to conduct him; the guide is a soldier sent by the officer who is to be relieved, as orderly-man to the major-general, who by having been at the post before can lead a new detachment to it.

If it is a post that is to be occupied for the first time, the officer is to ask the brigade-major for instructions relating to its defence; which being got, he must inspect his party, and take care that every soldier is properly equipped; his firelock loaded, fresh primed, and a good flint well fixed; his cartouch-box filled with cartridges; and that he carries provision for 24 hours, which is the time that detachments commonly continue, and are not allowed to go away to eat. Care must be taken to have spades, pick-axes, hatchets and wood-bills, one or two of each kind; and if any thing is wanting, to apply to the brigade-major for it, that they may have every thing necessary for entrenching.

One general rule in military projects that depend upon us alone, should be to omit nothing that can insure the success of our design; but to that which depends on the enemy, to trust something to hazard.

When an officer has inspected his party, he ought to get information from his guide, whether the way is broad or narrow, open or inclosed; if the enemy's posts are near; if they go on patrols, or see their parties in the day; and lastly, if he is to pass mills, farms, manors, &c. and from these informations take the necessary precautions for his march.

Secret marches are such as are to be made unknown to the enemy, to reconnoitre, to surprise, or to cross a country which they occupy. It is here that a commander has need of all his prudence to succeed and not to be betrayed. Before he sets out, he ought secretly to have procured the best information of the different routes that can be taken; the situation of the enemy's posts that are to be avoided; and the kind of country that is to be passed over. For better precaution it will be advantageous for the commanding officer to be provided with a plan in the manner to be explained in the following section (fig. 2.); and likewise to take along with him one or two sure intelligent guides.

When the whole are ready to march, the advanced guard A, (fig. 8) which should consist of cavalry only, should let out. It is surprising that all the authors who have wrote on this part of the art of war, have neglected to show sufficient attention to so essential a point: the greatest part are silent, and the

rest passing slightly over the different duties of this corps, are content that it should be composed of infantry; though, on the least reflection, in the most ordinary cases of a secret march, reason must determine that none but cavalry ought to be placed there, whether it be to stop passengers who may discover your route, or suddenly to attack an advanced guard of the enemy whom they meet face to face, or to harass their corps in order to gain time for your own to form: it is inconceivable, that for all these purposes, cavalry has greatly the advantage of infantry; who are by no means capable of running here and there to seize passengers, or of pouring suddenly on an advanced guard of the enemy; or of resisting their cavalry a moment in case of a sudden encounter, when they must expect to be thrown down and trod under the horses feet, and the corps attacked before the commanding officer has had a moment to prepare for his defence.

As examples serve best to illustrate opinions that have been seldom declared, the spirited behaviour of Cornet Nangle of the 15th regiment of light dragoons merits our particular notice, and will serve as a proof of the great advantage of having the advanced guard of cavalry. In the campaign of 1761, when the French army under the command of Marshal Broglie and the prince of Soubise were retiring towards Hoxter, where they passed the Weser, Prince Ferdinand followed close after them for several days, and on the evening before they gained the pass over the river, one of Prince Ferdinand's German aid-de-camps desired the grenadiers and Highlanders who were in front, to push on and take some of the enemy's baggage, which was a little way before them and but weakly guarded. They were immediately formed, and marched in a hurry over a plain with a thick wood in front, which they were told was clear, and had got within 400 paces of the enemy's baggage, when several squadrons of French dragoons rushed suddenly out upon them from the skirts of the wood upon both flanks, and were hewing them down without mercy, when Cornet Nangle with an advanced guard of twenty men coming up the hill got sight of the attack, and instantly rushing on, charged the French cavalry, who, startled at the briskness of an attack which they were not expecting, immediately reined back; when the rest of the regiment getting in view, came on; and attacking the French, drove them off, having killed and wounded a few, and taken some prisoners. The determined bravery of this young officer with his twenty men saved a great number of the grenadiers and Highlanders from being cut to pieces, and shows what may be effected by the sudden attack of an advanced guard of cavalry.

An advanced guard by night should be of double the force of one by day. In an open country, it is a matter of indifference at what distance they advance, provided they keep in view of the commanding officer, who should continually observe them; but in covered places, and in the darkness of the night, they should not be more than 50 paces distant.

This advanced guard should have an advanced corporal B, with six horsemen divided into three pairs; one in the centre B, the two others out of the road on the right and left at CC, to examine as wide as possible, silently

Plate
CCXCIX.

Plate
CCXCIX.

silently and attentively searching all hollow and covered places, taking care that there is nobody lying on the ground, or hid in dry ditches, behind trees or bushes. At the same distance of 50 paces upon the flanks of the corps, should march two wings DD, consisting of eight or twelve horsemen, each according to the strength of the corps, led by a non-commissioned officer. They can harraiss an enemy who may happen to rush suddenly out of ambushade, and give time to the corps to form. Each wing to detach two men EE, keeping 50 paces wide from the others, and preserving the same route as exactly as the face of the country will permit. At the entrance of the wood NN, the horsemen should spread, and close again at coming out, and do the same at meeting any little hills, to examine them on both sides. When they perceive any traces of a party, they should immediately communicate it from one to another, till it comes to the commanding officer.

The advanced guard ought to march slowly, and the commanding officer at the head of the corps should follow at the same rate, so that the rear of the detachment may not be obliged to gallop. As the rear-guard H is only established for form, there is no need of its being numerous. The officers and quarter-masters should be careful to keep the men from sleeping, as a horse is easily hurt under the irregular motions of a sleeping rider, which retards the march. The whole corps should be forbid to smoke or speak; and if any one is obliged to cough or spit, let him cover his mouth so as to make no noise.

When the corps is numerous, the cavalry should march by squadrons, the infantry by platoons, to follow alternately, so that each platoon of infantry FFF may march at the head of a squadron of cavalry GGG; which disposition will preserve the whole at an equal pace, and keep them readier to form in case of meeting the enemy, or being suddenly attacked, as we are about to mention.

When the advanced guard perceives an enemy at a distance, whether it is day or night, they should not pursue them for fear of falling stupidly into some ambushade, if it is not in a country that has been well examined; but if they meet them suddenly face to face, as may happen at the entrance of a hollow way I, opening obliquely upon yours, then your advanced guard, without deliberating about their strength, should instantly rush upon them. This manœuvre cannot fail against infantry, and gives a great advantage in a rencounter with the cavalry; but if your advanced guard falls back, they expose the whole body to be defeated with them.

When the commanding officer sees the action of his advanced guard, he will instantly turn the infantry on the side of the road most proper to protect them from the enemy's cavalry, and will form them quickly at the side LLL, or on some neighbouring height MM. If it is day, they ought to face the cavalry, stooping down till the instant of the attack, while the first squadron advances to sustain the advanced guard. If the enemy appears desirous to renew the charge, and obstinate in disputing the passage, you may make use of a feint, and by falling back bring them opposite to your infantry, who will have them in the flank, and by a well-placed fire put them instantly in disorder.

Your cavalry profiting by this, must immediately face about, and fall upon them with all possible violence; which cannot fail to complete their defeat.

All villages, hamlets, and houses, should be avoided, especially by night (which is the most common time for the partisan), to avoid being discovered by the barking of dogs, or being seen by peasants who can inform the enemy. You will see equally how dangerous it is to keep the great roads by day, or to cross places that are too open in an enemy's country.

If you cannot avoid passing through a village, it should be done in a hurry, marching confusedly, very close, and filling up the whole breadth; by which you will conceal your strength from the peasants; some officers should remain at coming in, and in the rear, till the whole are passed, taking care that no one stops or withdraws. The same care should be taken at every road that opens upon your route. At the approach of every place that is covered or hollow, such as house, wood, gully, &c. they should halt till it is well examined, and continue attentive in passing it.

At the passage of defiles, bridges, or fords, the advanced guard should stop at two paces, and form till the whole corps is passed and in order. The ancients employed dogs to discover the enemy in ambushade; but it will be well to distrust such spies, and to suffer none with the corps, as there is nothing more dangerous; their disposition leading them to bark at meeting the least animal, will furnish the enemy with a thousand opportunities of observing you, before you can know where they are.

You should always detain the guides that were taken at setting out; but if necessity requires another, the quarter-master should go and take one without making a noise, and lead him a round-about way, that none of the peasants may discover either your party or route. If any of the party discover passengers in sight of the march, they should be stopped and brought to the corps, and care taken to prevent their escape.

The party should never refresh in a village, but in a wood by day, and open country by night, causing every necessary to be brought them from places in the neighbourhood, which ought to be received from the peasants at a distance, so that they can neither discover the number nor quality of your corps. During the whole time of stopping, you should not be sparing of centries, and have always six horsemen ready to secure any person by whom you imagine you are perceived; when their number becomes considerable, they should be tied together, and great care taken that none escape till the stroke is struck. The officers should be equally attentive that no soldier gets out of sight; and if they meet a deserter from the enemy, he should be conducted immediately to the corps, and then to the army, under the care of a non-commissioned officer.

When necessity obliges you to stop in the neighbourhood of some farm or hamlet, you must take possession of it, and carry off the farmer or chief of the place at going away, threatening to kill him and set his house on fire if any one stir from the place before he is released. Every horseman should take care to have a spare fore-shoe, and a peck of oats.

The best season for secret marches is the cold time of winter, when neither peasants nor their dogs stir abroad,

abroad, and the enemy are quiet, only thinking how to preserve themselves from the cold, which your people get the better of by marching. When you find yourself in the night in some stony place near a post of the enemy, and you are afraid of their hearing the noise of your horses feet, it may be deadened by stretching the men's cloaks on the ground, which was an expedient of great use to Mr Jency in Italy.

If an officer of the infantry marches a detachment to relieve a post at a distance, he should not mount his horse till out of sight of the camp, and should dismount on coming in sight of the post; but if it is only about a league distant from the army, and near the enemy, it is better to go on foot, so as to be less encumbered in case of engaging with any parties of the enemy. The men should not be pressed too much for fear of lagging in the rear, but should march close without stopping, and in as many files as the roads will permit, keeping profound silence, that they may hear any orders that are given.

An officer who marches at the head of a party ought to keep exact order and profound silence, that they may be in a state to execute whatever he may order for their defence; but in giving his orders, he should take care to do it with a firm and determined countenance, so as to make the soldiers think that he is sure of what he is about, and that nothing better can be done. When the men see their officer hesitating, or varying in his orders, they imagine he does not know what to do; and seeing him disordered, they become so. It is upon such occasions that an officer should be ready to restrain his party, and make them instantly obey. The danger is greater on a march than in an attack. Here the soldiers have their arms in their hands; and, seeing the enemy before them, are ready to engage. It is otherwise on a march; they are less upon their guard, and have not their arms in readiness: then, says Vegetius, an attack confounds them, an ambuscade disorders them. An officer ought therefore to take every precaution in examining by his advanced guard, all places that may conceal any of the enemy.

As it is difficult, or rather impossible, to examine all the villages where it is necessary to pass, and where the inhabitants are often to be dreaded more than the enemy, an officer had better avoid them if possible, by making a circuit at some distance, and coming to the road afterwards. The most experienced soldiers should be employed to make discoveries, with orders not to stop to drink or amuse themselves, to talk with the peasants, or lose sight of the detachment; but to stop every person that would pass before them, and come quickly to tell the commanding officer what they have perceived.

But as the greatest precaution cannot prevent an officer on a march from being attacked, it is necessary, as soon as he perceives the enemy, to observe if the party is superior to his detachment; whether it consists of cavalry or infantry, or both together. If it is cavalry, and superior, there is no necessity for being discouraged; but on the contrary he should profit by every advantage that offers, by gliding into land that is furrowed, uneven, cut, and difficult or inaccessible

to cavalry; or if the country is inclosed, he should line the hedges, and cheer up his soldiers by some encouraging language, while he dispatches a trusty fellow with advice of his situation to the general. If the enemy march up to him in this situation, he must do all that he can to sustain the attack, by ordering his party not to press upon one another, to keep up their fire, and not to discharge their pieces till they are at the muzzles.

Every country presents some natural fortifications which, however despicable they may seem to be, there are brave people who have defended them with extraordinary valour. The duke de Rohan in his memoirs makes mention of seven soldiers in a wretched cottage of earth near Carlet, who stopped the army of the Marshal de Themines for two days, though of 7000 foot and 500 horse.

When you have the advantage of rocks or other obstacles to the acting of cavalry, continue the route as near as possible, keeping the party close, and always ready to receive the enemy. If the number of the enemy's cavalry do not exceed your party, you may continue your route; and keeping your men close together and prepared, they will not venture to attack you. If the men could be depended on, and you could scatter them so as to leave no particular object for a body of cavalry to charge, they would have a still greater advantage; but this manœuvre is only for a small detachment, and would require particular instruction for the execution of it, which is impracticable with an occasional detachment.

If an officer sees no means of possessing an advantageous post, or of getting to the post he was detached to, he can do nothing better than to retreat to the camp, along some river or wood, to prevent being broken; but if he is so closely pursued that he cannot avoid being beat or taken, there is no better manœuvre to imitate than that of the Barbets (A); who scatter themselves, and retire from tree to tree, from rock to rock, and destroy a party, who can neither beat them, nor take one of them.

The moment of taking possession of a post is the most critical that a detachment can have; officers have been frequently attacked at the very time they thought they had nothing to do but quietly take the necessary measures for remaining in safety.

If the party which arrives at a post is to relieve another, the officer that is to be relieved gets under arms as soon as his sentries give notice of the approach of the relief. The detachment being known, they are permitted to enter and occupy the post in the room of those that are to depart; at the same time, the corporals go to relieve the sentries, and the officers and serjeants give the counter-sign, with the detail of all that is to be done at the post by day or night. He ought likewise to get information from the officer he relieves, if the enemy make incursions in the neighbourhood; if their guards are distant, whether cavalry or infantry, and whereabouts placed. After these precautions, let him guard against his post being surprised.

The sentries being relieved, the officer that is to go out must form his detachment, and return to camp with

(A) They are peasants subject to the king of Sardinia, who abandon their dwellings when the enemy take possession, and are formed into bodies to defend the Alps which are in his dominions.

with the same precautions as in coming. The new detachment remain under arms till the other is gone 50 paces; then the officer is to make them lay down their arms against the parapet, putting their haversacks against the gun-locks, to prevent dust from spoiling them, or the dew of the night from wetting the powder. In an open country without fortification, the men must not go to any distance from their arms when they lay them down in the day, and keep them between their knees when they sit round their fires in the night, with the locks inward, to prevent accidents.

SECT. V. *Of Reconnoitring.*

PARTIES ordered to reconnoitre, are to observe the country or the enemy; to remark the routes, conveniences and inconveniences of the first; the position, march, or forces of the second. In either case, they should have an expert geographer, capable of taking plans readily: he should be the best mounted of the whole, in case the enemy happen to scatter the escort, that he may save himself more easily with his works and ideas.

All parties that go for reconnoitring only, ought to be but few in number. They should never consist of more than 12 or 20 men. An officer, be his rank what it will, cannot decline going with so few people under his orders; the honour is amply made up by the importance of the expedition, frequently of the most interesting consequence, and the prospect to recommend the prudence, bravery, and address of any officer that has the fortune to succeed.

It must be evident that the success of such a commission depends upon secrecy, and that it is impossible to fulfil the intention without keeping out of sight of the enemy. It is incontestable, that a numerous party cannot glide along so imperceptibly as a small handful of men. As these detachments must finish their course quickly, it is necessary that they should consist of cavalry only; but if they are to go far, they may increase each with 30 foot, to remain in ambush about half way, in a wood or covered place, with whom the cavalry can leave their provision they brought with them.

An officer charged to reconnoitre in front, should take his instructions in writing, and set out at such time as to arrive at the place proper for beginning his observations at day-break. Every time that he has occasion to stop, the party should face toward the enemy, and send a non-commissioned officer with two horsemen to run over the neighbouring heights, and closely examine the environs. - When near the enemy, avoid stopping in a village.

The officer, and geographer who is supposed to be present, should remark every interesting particular: The heights, woods, ponds, morasses, rivulets, rivers, fords, bridges, roads, crossings, difficult and dangerous passages, by-ways, meadows, fields, heaths, gullies, hills and mountains; the distance and strength of villages, hamlets, houses, farms, and mills; what sovereign the country belongs to, and what are its productions.

If the enemy comes in sight, the officer should quickly assemble his party, though his reconnoitring be not finished, and let him retire to his infantry, if he placed any; but if not let him gain some other

place that he has chosen for a retreat. After being refreshed, let him go back with the cavalry to finish the reconnoitring; but if he was obliged to return quite to the post, he should not go back till next day. Mid-day is the time of being least incommoded, as detachments are less frequent at that hour. The commanding officer ought always to avoid coming to blows, even though he thinks himself secure of success, unless he happen to be on his return, and near to his post, so that he foresees the grand guard, hearing the firing, cannot fail to run to his assistance. If obliged to engage with a party who are cutting off your retreat, and that no other means is left of turning them, you must risk all without hesitating, by rushing on, and try to save the geographer with the fruits of his commission, especially if the reconnoitring was of importance to the general of the army, and merits the sacrificing a dozen men, which they can easily retrieve on another occasion.

When they go to have news of the enemy, they ought to approach as near as possible, but cautiously: day-break is not the time proper for such a purpose, because at that time the enemy send their different parties and patrols to make discoveries; you should therefore prevent them by approaching in the night. You may easily reconnoitre their position and extent by their fires, which they never extinguish at the head of the guards and pickets; and you may easily remark if they are about to change their position, by hearing a more than ordinary noise; besides, as it is easy to approach by night, you may discover a number of things by the light of the fires.

The officer and geographer must take care to remark every thing, and let nothing escape their memory; but the best time for the geographer is by day in the mountainous country, where they may slip along from one mountain to another, from mid-day till three o'clock, which is the most favourable time to shun parties, who seldom stir from the army at that time of the day. They must stop all who pass in sight of the party, and release none till the retreat is secure.

A partisan ought not to neglect to reconnoitre every place round his post for two or three leagues, or farther, if it is possible on the side of the enemy; and for that purpose, employ the method of Mr Jeney for getting intelligence without approaching, and taking plans and observations: so that if the enemy come to possess the country, you may have every necessary instruction for making approaches to surprise them, without having recourse to the peasants.

During the campaigns that Mr Jeney made, he often examined the enemy's posts without approaching, in the following manner, which he recommends as infeasible, he having always succeeded.

I suppose myself, says he, with my party at Soest in Westphalia A, (fig. 2.) and the enemy posted at Bervick B, two leagues from me. To know the situation of this place without stirring from Soest, I take the map of the country; and from Soest as centre, I draw a circle whose circumference passes half a league beyond Bervick. I draw a circle of the same size upon a leaf of paper, to make my plan as in (fig. 2.), and then place Soest in the centre A; and I mark all the villages which I find in the map

near the circumference, upon my plan, with the distances and bearings as they are represented in the map, making use of a pencil to mark the places DDD, so as to correct the errors more easily which the map may have led me to make.

Having thus formed my plan, with a scale of two leagues (which is the distance I suppose Bervick), I go to the burgomaster of the town of Soelt, where I cause some of the most intelligent inhabitants to come, speaking to them freely, and openly induce them to communicate all the information I have occasion for.

The better to conceal my designs, I begin my reconnoitring by Brokhufen, a village distant from the enemy. I ask the distance from Soelt to Brokhufen; if they say it is seven quarters of a league, I correct the distance of my plan which made it two leagues: then I inform myself of all that is to be found on the road from Soelt to Brokhufen; chappels, houses, woods, fields, orchards, rivers, rivulets, bridges, mills, &c. If they say that at a half league from Soelt they pass the village of Hinderking, I mark that place upon my plan. I ask if the road from Soelt to Hinderking is crossed by any other road; if there is any morass or heath; if the road is inclosed, paved, or straight; if there is any bridge to pass, and at what distance. I take care to mark every thing in my plan, forgetting nothing, even to mills, bushes, gibbets, gullies, fords, and every thing that can be got from their informations; which will probably be perfect, because one always knows more than another. I continue my questions from Hinderking to Brokhufen; and advancing by little and little, observe the same method on the roads of the other villages round, marked DDD. In this manner I cannot fail to acquire an entire knowledge of all the places; besides, I find myself imperceptibly instructed in the position of the enemy, by seeing the different routes by which I can approach most secretly.

It is plain that such a plan must be very useful to regulate secret expeditions. It is chiefly useful, not to say necessary, for a commander of a party, who can give more ample and precise instructions to his officers, by accompanying them with a copy of the routes marked out, which they can consult even in the night, if it happens to be clear; by which they will be guarded against being deceived by ignorant or treacherous guides, which occasion the mistakes of so many who go unprovided with such helps.

There is still another means to secure a reconnoitring party; which is, to compose them of people who speak the language of the enemy, and give them surtouts of the colour of a regiment of the enemy, and cockades the same. This scheme may be carried so far as to line the surtouts with the colour of another regiment of the enemy, provided that by turning the surtouts, they appear to be a different corps, and deceive guards, spies, and peasants, and confound their reports.

An officer who goes to reconnoitre a post which he intends to attack, should set out the beginning of a dark night, and give particular instructions upon the subject to those he takes with him to assist in making discoveries: such as examining the places by which they pass, to approach the post; sounding with long sticks if there are any traps or covered ditches into which they can tumble; to leave branches of trees

with their leaves on, to serve for a mark where they find any, against they come to make the attack; to observe exactly where the sentries are posted, and how many there are of them, and how far distant from one another; to advance even to the ditch of the entrenchment, and sound with a stick or plummet to know the depth of the water; to examine if the post is fraied or palissaded, made with earth or fascines, or covered with masonry; in which last case, they must observe its height, to proportion the ladders accordingly. They ought likewise to know how many men are to defend it; in what they are negligent; if they are near assistance, and have cannon. It is on all these heads you can go and examine yourself, or be informed by the reports of deserters or peasants, so that you may form your scheme of an attack. If you are only instructed by information of others, be careful how you believe people too readily who may wish to betray you, or come only in hope of a recompence. They should be questioned separately, writing down what they say; and by comparing their informations, judge of what is true or false.

SECT. VI. *Of the Defence of Posts.*

When a partisan has taken every precaution that prudence suggests in reconnoitring a place where he would fix a post, he is to take possession in the following manner. The infantry remain under arms in the middle of the place, the cavalry to patrol without, while the commanding officer, escorted by a dozen horsemen, goes to examine the environs to make his arrangements; having sent several small detachments before, to cover him in time of reconnoitring.

Having remarked the places proper for his guard, defence, and retreat, as well as the dangerous ones by which the enemy can make approaches secretly to surprise him, he should choose the most convenient in the front of his post to fix his grand guard D, (fig. 1.) which must face the enemy. He must mark the heights for this guard to place their vedettes EEEE, and regulate the number according to the exigencies of the situation. In a covered country you must not be sparing of them, and must reinforce every guard. At 50 paces before the front of the grand guard, a subaltern or non-commissioned officer with eight horsemen should be always ready to set out at K, to go and reconnoitre, when the vedettes have observed any party.

The grand guard being fixed, you should form another in the middle of the village, called the *ordinary guard*, composed of cavalry and infantry, placing sentries at the entries, and vedettes all round; the last at such distance as to see one another. A picquet should likewise be fixed before the quarters of the commanding officer, which should be near the ordinary guard and the whole corps. In the day, half the cavalry of the picquet must keep their horses bridled and ready to mount; but if the enemy is near, they must remain on horseback, the other half to unbridle till the hour of relief.

According to the arrangement we have given for composing the corps of a partisan, the grand guard may consist of a captain, a first and second lieutenant, a quarter-master, two serjeants, four corporals, a trumpeter, farrier, and 52 private horsemen. The

ordinary guard to have cavalry equal to the grand guard, with a captain, a first and second lieutenant of infantry, two serjeants, and 60 men, including four corporals, two lance-corporals, and a drummer: the picket to consist of the same number of cavalry and infantry as the ordinary guard.

If there is any dangerous place capable of covering the approaches of the enemy in the environs of the post, and out of the circuit of the patrols, there should be a guard placed there, more or less strong according to the importance of the place, and care should be taken to preserve the communication. The guards and pickets being placed, the detachment that was sent out on the roads must be called in, and then go to work to lodge the party in the gardens that open upon the country, and the commanding officer's quarters; beating down hedges, filling up ditches, and levelling a piece of ground large enough to draw up the whole corps. The horses to be put under cover in barns contiguous to the gardens; but in case there are no barns, they may substitute sheds open on one side, that the horses may go out altogether in case of an alarm.

The officers should occupy the houses in the neighbourhood of the sheds, and one of each company remain day and night with the company, to prevent any of the men from entering the village without leave, upon any pretence. The commanding officer must acquaint the officers of his having chose the place M for the rendezvous in case of a retreat; which ought to be at some distance from the village, and on the side he judges most convenient for retiring to the army. At sun-set the grand guard to return to the post and join the picket, the one half of each to mount alternately till day-break, and then the grand guard to return to the place they possessed the day before. The sentries and vedettes should be doubled, and all the passages shut up with waggons placed in two rows, except one for sallying out at, in case of a retreat, made wide enough for the passage of the patrols or the whole cavalry.

The corporals of the ordinary guard should lead the relief of the vedettes every hour, setting off together; but when they come to the passage of the post A, (fig. 1.) they must separate into two parties, the one to the right to relieve the vedettes BBB, the other to the left for the vedettes CCC; then each of them with the parties they have relieved should go on at their head a quarter of a league, by the two routes pointed out in the plan, to examine the environs, supposing an hour to each. Besides this reconnoitring, the captain of the grand guard should send two patrols in the night. To fill up the intervals, they should set one about half an hour after the corporals, and make the same round. At returning to the post, the corporals to make their report to the officer of the ordinary guard; the conductors of the patrols to the captain of the grand guard.

A little before sun-rise or sun-set, a grand patrol detached from the corps should be sent under the conduct of an officer to search the whole environs of the post minutely, especially the dangerous places, because at these times the enemy are most likely to attempt a surprise. If the patrols discover them, they will be in a state to repulse them, or at least to harass them

till the commanding officer, upon the first notice, draws up the whole corps. The officers should take great care to instruct the sentries in their duty, explaining it to them every time of their mounting, and forbid them to smoke, as the least fire can be easily perceived in the dark, and serve to direct the approaches of the enemy. No sentry to move more than 50 paces to the right, and as many to the left of his post; and let the weather be ever so bad, he must not get under cover. No one to be allowed to go out of the post without leave of the commanding officer; and to prevent desertion or marauding, the sentries and vedettes must be charged to let no soldier pass.

The vedettes must stop all passengers, and take them next to the sentry, who must call a corporal to conduct them to the commanding officer. If there are a great number passing at once, the vedette at the challenge must hasten to stop them at 100 paces, till the officer has sent to reconnoitre them; but if he finds them to be a party of the enemy, he must fire upon them and retire. At the first alarm, the grand guard and picket ought to mount, and each of them to detach a subaltern officer immediately at the head of the best mounted horsemen, to go quickly to encounter the enemy. The rest of the grand guard and cavalry of the picket to follow immediately, led by their captains to sustain the first detachments, to repulse or keep back the enemy as long as it is possible, and give time to the commanding officer to form the whole corps.

If the commanding officer observes that the enemy are of no very extraordinary force, he must without hesitating put himself at the head of his cavalry, and instantly charge them, pouring upon them with his whole force, which is the best way to succeed; and in the mean time, the infantry should form to sustain the cavalry. One essential circumstance should not be forgot here, which is, that at the going of the detachments of the grand guard and picket, all the infantry of the picket should march immediately to the place appointed for the rendezvous in case of a retreat, and a strong detachment of cavalry should follow to occupy the place. If it is at the entrance of a wood or some covered place which the enemy may occupy, and thereby cut off your retreat, you must prevent it by fixing the infantry of the picket in the post, to remain day and night, with a lieutenant at the head of 20 horsemen to clear round it. If the enemy is too superior, and appears to form an attack on that side, the commanding officer should get there before with all his force to oppose them, till all his detachments join, and then regulate his retreat, as will be seen in the section of the Retreat.

To be better secured in a post which you expect to remain in for some time, and where you find that the enemy will not fail to disturb you, it will be proper immediately to employ some of your people with the peasants, to form some intrenchments in a hurry in the most dangerous places, to have breast-works of felled trees in the woods; herbes placed in the fords; pits dug at the entries and plains without defence; so that the cavalry coming full speed to charge you, may tumble in. If there happen to be a bridge either in the front or on the flanks of the post, as at N, by which the enemy can facilitate their approach or retreat, it must be instantly destroyed, unless you find it

may be of use, and necessary to fix a good guard on it.

To regulate the attack and defence most advantageously, you should take care to observe the places by which the enemy can approach, and form a plan of operations for cutting off, or taking in flank the different routes which he can attempt. You should inform your officers, and not fail to hearken to the advice of those, whose talents, genius, and experience, render them competent judges of your designs. These arrangements will be of great use in surprising the enemy's parties, who will come from time to time to reconnoitre the post. If the enemy approaches in the night, take care how you attack him; you cannot reconnoitre his force, and you ought to suppose that he is informed of yours.

Do not suffer any suspected woman to approach the soldiers; their visits are dangerous in debauching your people, and the enemy frequently employ them to discover your strength. Let no deserter stop in your post; and if he comes in the night, keep him till day-break is near, and then send him to the army. Every party that approaches your post will profess belonging to you; but if they are not provided with a proper passport from the general, or if you do not know any of the officers, trust neither to their word nor uniform; desire them politely to return the way they came, telling them, that if they do not, you will treat them as enemies; and take care that your party remain under arms till they are out of sight of all your guards.

Even if it is another party of your army approaching your post, as soon as you are acquainted with it, you ought to reconnoitre them, and follow or receive them with all the attention which war requires.

When a partisan has taken all these precautions, he may reckon himself secure of never being surprised. If in a country the most exposed, or the most covered, by executing every point of the service as has been mentioned, the enemy cannot approach your post nearer than a quarter of a league without your being informed by the noise of the vedettes and patrols, who cover your post day and night more than a quarter of a league round, which is sufficient to guard against surprise, five minutes being sufficient to form, and ten being still left to deliberate upon the part that is to be taken, whether to attack, defend, or retire.

When a partisan happens to establish his post in an enemy's country, it is then his duty to take care of the subsistence of his corps, and to take every proper measure to provide his people with necessaries: for which reason he should send some parties as far as possible towards the enemy, to summon the chiefs of the villages to deliver forage and provisions in proportion to their abilities, taking care to be sparing of the nearest places, and more particularly of the post itself, which ought not to be touched but in the greatest extremity. A partisan cannot be too diligent in giving the general an account of his position, projects, success, and all his operations, and therefore will take care to preserve his communication with the army.

These instructions may serve for the corps of a partisan according to the proposed arrangements; but partisans of less force must regulate their precautions according to their strength; and detachments of 30, 50,

or 100 men, will seek to post themselves in redoubts proportioned to their number, or in mills, farms, hamlets, detached houses, churches, church-yards, &c. observing that the more a post is extended, the more care and fatigue it requires.

The principal object for an officer that is detached, says Monsieur Vauban, is to foresee every troublesome event. The want of exactness, and the smallest relaxation in the service of out-posts, may have the most fatal consequences; and history furnishes a thousand examples of camps being surprised, and armies cut in pieces, by the negligence of detachments that ought to have watched for their preservation.

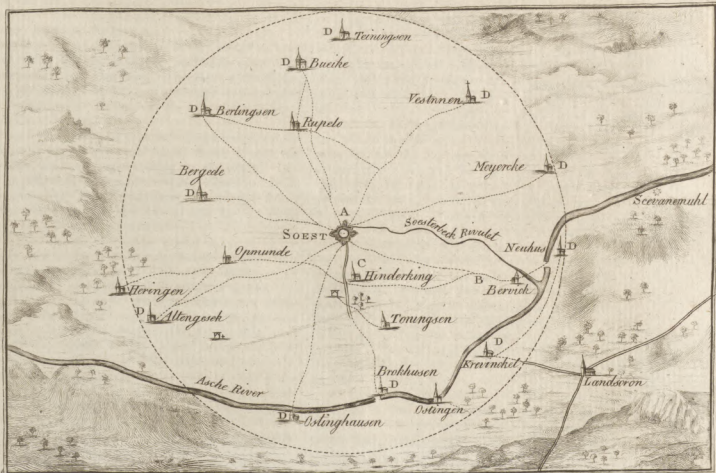

The manner of relieving detached posts has been mentioned; but if an officer is detached to a mill or house, let him draw up his party about 15 or 20 paces from the post, and send a serjeant or corporal with five or six men to search the chambers, cellars, and baras: which being done, the sentries must be placed, the post taken possession of, the arms ranged so that every one can find his own without confusion, and the inhabitants lodged in some other house; and then entrench himself according to the rules given.

If an officer is to fix in a village where it is difficult to examine every place where the enemy may lie in ambush, he should fend for the magistrates to come and speak with him, while his party remain drawn up at the end of the village, that they may declare if they know whether there are any of the enemy's parties, suspected persons, or concealed arms in the place; which being done, the sentries are to be placed, and the party to take possession; putting small detachments of five or six men, more or less, according to the strength of the party, at the avenues; and examining the church, or any detached house, to make the principal post in case the advanced posts are forced. The men best acquainted with the duty should be planted on the most exposed and distant places, so as to see all the approaches; and sometimes in trees, that they may see at a distance, and remain concealed from the enemy.

If he finds any place near him where the enemy can lie concealed, he should place a corporal with six or seven men there, with orders to fall back upon his post if attacked, or remain till they find themselves disengaged. The soldiers of this lesser post should take care to make no fires, because it would serve for a guide to the enemy to avoid them when they want to fall upon the principal post; but fires may be lighted in the places where they have no guards, to make the enemy think they have them every where, at the same time placing soldiers in ambush where there are none lighted. This scheme may serve for all posts in a level country, where two or three soldiers should be kept going all night to stir up the fires.

The exterior arrangements being made, and sentries placed on the avenues, bridges, and steeples, the works for fortifying the post should be marked out, and executed by the workmen, and the magistrates ordered to send straw to the nearest houses for lodging the soldiers, who must never absent themselves. The officer must always be in readiness to go where his presence may be wanted, and make his serjeants and corporals frequently go the rounds.

Monsieur Vauban says, that if an officer is to remain but four hours in a post, he ought to intrench; and he should

should cause the works which are to be constructed to be well executed, so as to defend every place where the enemy can come. Monsieur Folard gives an excellent maxim, to attack an imaginary post, that we may be able to defend a real one. And the Baron de Travers says, that with regard to the strength and means of resistance in posts, they should be in proportion to the force the enemy can bring against them. If to pass only some hours in a post, it is a good way to make a parapet of felled trees; or if it is in a village, to intrench a detached house.

The way to guard against being surpris'd, betray'd, or made prisoner, is to take precautions against all that the enemy can undertake; and whatever distance he may be at, we ought not to found our security on probabilities, but extend them even to possibilities. Neither stranger nor soldier of any other party should be admitted into the post; and the roll should be call'd three or four times a-day, that the men may not absent themselves: he should likewise examine the sentries, to see whether they are acquainted with the detail of their duty, and should show them how to defend themselves in case of being attacked; observing to them, that if the enemy make such a manœuvre, they should oppose such another; if they try this scheme, to resist with that, and deceive them at every step. He may make some of them try to scale the intrenchment, to show the difficulty of mounting it; and by exercising them in this manner, he will prepare them to resist the enemy; it will flatter their vanity, and give them a confidence in him. But let him take care not to be too familiar, lest in a brisk attack he orders something not to their mind, when, instead of obeying, they will resist his orders, and mutiny; but when he has shown his soldiers the advantage of a party that are entrenched, over those who are exposed in the attack, he must take care to preserve subordination, and not allow himself to fall into the snares of the enemy.

An hour or two before day, the men should be kept alert, sitting on the banquette near their arms; and the patrols sent at that time, rather than in the night, to march slowly, to listen attentively, and examine every place round the post where a man can conceal himself.

It frequently happens that two armies are encamped opposite to one another, and have several posts on the same line, and two patrols meet in the night. As it is impossible to distinguish whether they are friends or enemies, they who first discover the others, should conceal themselves on the sides of the road, behind bushes, or in a ditch, to examine if they are stronger; and in that case to let them pass in silence, and return another way to the post to tell what they have seen: but if they find them weaker, he who commands the patrol should make the signal which is ordered for the patrols of the night, which is commonly a stroke or two on the cartouch-box or butt-end of the fire-lock, which is answered by an appointed number; but a word is the safest. If the patrol does not answer, they should advance upon them with fixed bayonets, fire upon them if they see them retiring, and make them surrender. In the war of 1745 in Italy, there were old soldiers who used to beg for this employment, and took pleasure in it.

If detached opposite to the enemy, it is to be pre-

sumed that you may be attacked: therefore small detachments should be advanced between the sentries in the night, about 30 or 40 paces from the post, with their bellies on the ground, in these places where they imagine the enemy may come; with orders to those who command these detachments, to make a soldier reconnoitre any parties that are seen, so as not to confound their own patrols with the enemy's parties, and to retire to the post on the first firing.

In villages there should be great care taken of suspected persons, or of the peasants revolting; and for this purpose, you should make the magistrates order two peasants, the best known in the place, to be put on duty with the sentries of the party, at the passages left in intrenching. These peasants, whom the magistrates must cause to be relieved every two hours, should be charged to recollect all who pass out or in of the village; and both one and the other must be told, that they shall be answerable for all the accidents that may happen from the treachery or negligence of those sentries who have let enemies in disguise enter the village.

They must likewise order the soldiers who guard the intrenchments, to let no peasant approach, and to shut up the passages with two trees across in the night, and not to open them till day, except for the passing of the patrols. They must examine with iron spits, or their swords, all carts that pass loaded with hay, straw, or casks, or any thing that can conceal men, arms, or ammunition.

The inhabitants should be prevented from making processions, holding fairs or markets; because under favour of these assemblies the enemy may often enter and seize posts.

An officer cannot watch too carefully to prevent schemes that may be contrived against him; and the attempt on Brisac, in the month of November 1704, is so much to the purpose, that it ought not to be passed in silence. The governor of Fribourg having formed the design of surprising Brisac, set out in the night of the 9th or 10th of November, with 2000 men, and a great number of waggons loaded with arms, grenades, pitch, &c. and some chosen soldiers: all these waggons were drove by officers disguised like waggons, and were covered with perches, which had hay placed over them, so that they appeared like waggons loaded with hay coming in contribution. They arrived at the new gate by eight o'clock in the morning, under the favour of a thick fog: three waggons entered the town, two full of men, and one with arms, when an Irishman, an overseer of workmen, observing 30 men near the gate, who, though they had the dress, had not the manner of peasants; he asked them what they were, and why they did not go to work like other people. Upon their not answering, and appearing confounded, he struck some of them with his cane; upon which the disguised officers ran to the arms which were in the waggon next them, and fired 15 or 20 shot at him within half a dozen paces, without wounding him. The Irishman leaped into the ditch, where they likewise fired several useless shot at him, while he called *To arms, to arms*, with all his might.

At this noise, the guards of the half-moon and the gate ran to arms, and would have pulled up the draw-bridge, but were prevented by the waggons which the enemy had placed upon it. The officers and soldiers

who

who were in the waggons, rushed out with their arms, and having joined the rest, attacked the guard commanded by a captain of grenadiers; but being repulsed, and five of them killed, the rest were dismayed, and fled either into the town, or out into the country. The captain of the guard made the first gate, which was a grate, to be shut, across which the enemy, who were upon the bridge, fired at all who appeared; and having left the half of his guard, he mounted the rampart with the other half, and continued firing upon the enemy. A lieutenant who commanded 12 men of the advanced guard, was attacked at the same time by an officer who presented a pistol to his breast; but snatching it from him, he fired it at him, and killed him: this lieutenant defended himself to the end of the action; but having received several wounds, he died that day.

Upon hearing the noise of the surprise, the commanding officer of the place distributed his garrison to their proper posts: and having made every disposition necessary for his defence, the enemy saw that their design had failed, and retired in disorder, leaving a number of waggons behind them, and more than 40 soldiers who were killed or wounded. Such was the enterprise on Brifac, which failed by a trifling accident.

Another example will prove how necessary it is for officers in detached posts to take every precaution. Captain Vedel being detached to a village, where the curate of the parish had obtained leave from the commanding officer in the country to make a procession of the penitents of a neighbouring convent to a chapel in the village which he named, alleging that it was an annual custom: but captain Vedel, astonished to see such a numerous procession composed of the peasants, called to arms, and having drawn up his party of 50 men, disconcerted their scheme. Many of the penitents whom he stopped, were found armed with pistols and swords; with which he acquainted the commanding officer, who immediately caused the curate and several of the penitents to be hanged.

This example, and many others which might be cited, show that an officer who commands in a post cannot be too much on his guard to prevent his falling into the snares which the enemy prepare for him, as the seizing of a post, of however little importance it may seem, may be attended with the most troublesome consequences.

Henry IV. of France lost Amiens in Picardy by a waggon letting fall a sack of nuts as if by accident; and when the soldiers of the guard were picking them up, the Spaniards, who had disguised themselves like peasants on purpose, rushed out of a house near the gate where they had been in ambush, put them to the sword, and carried the town.

These instances, with many that could be mentioned, show that we cannot be too distrustful of the numberless ways there are of being surprised. If peasants come to visit their friends or relations in the village, the sentries should stop them, and acquaint their officer, who should not allow them to enter till the magistrates, curate, or responsible inhabitants, answer for them; and this permission to be granted only on working days, and not on Sundays or festivals, on account of their being unemployed these days.

In an enemy's country, the inhabitants are always

ready to revolt and betray; therefore the commanding officer ought to take one or two of the magistrates children, or three or four of the most considerable families of the village, and keep them in the principal post as a pledge of the fidelity of the inhabitants. The children (to whom they should take care to do no manner of hurt) should only be kept half a day each, and changed for some others. The commanding officer should forbid the inhabitants to assemble in taverns or public walks, or any place whatever, and cause these orders to be fixed up at the door of the church. If they are seen to stop and converse at coming out of church, or in the market-place, let the patrols oblige them to retire. The tavern-keepers and all the inhabitants must be forbid to receive any stranger without acquainting the commanding officer. None to be permitted to stir abroad after retreat beating, on pain of being killed by the sentries who see them, or stopped and conducted to dungeons by the patrols; who ought to march slowly, stop from time to time to hearken if they hear any noise, go over all the quarters that are marked out to them, and give an account of any thing they have discovered that can cause any alarm in the post.

If fire breaks out any where, or the inhabitants quarrelling among themselves, an officer should take care how he sends a party to their assistance, because these are frequently snares of the enemy to divide the strength of a detachment on purpose to attack them; he should therefore ring the alarm bell, make all the different posts get under arms, and order those who command them, to make the soldiers remain armed against the parapet, so as to observe what passes without the village. The soldiers of the principal post should likewise get under arms, and the officer detach four or five men with a sergeant or corporal to part the fray, or set the inhabitants to work in extinguishing the fire.

As all the necessary precautions for the safety of a post are too many to have them executed by giving them verbally, the commanding officer should give his orders in writing, and have them fixed up in all the lesser posts. One thing to which officers who are detached to a village should give particular attention, is, not to vex the inhabitants by making them furnish too much: whatever they are allowed by the general to exact, such as firing, forage, candle, &c. for the guards, should be demanded in proportion to the abilities of the inhabitants; and an officer cannot be too delicate in preserving the character of a gentleman in ordering contributions, and preserving the inhabitants from being robbed, or treated ill by the soldiers.

It is not sufficient for the preservation of a post, to raise intrenchments, nor to take every precaution against being surprised. As the enemy must attack with a superior force, your dispositions must be made in such a manner as not to confuse one another, and every one being properly placed, contributes to the common safety.

If it is a doubt, or other intrenchment of earth that is to be defended, seven or eight trees with their branches should be kept in reserve, to throw into the breaches the enemy may make, and the parapet kept well lined with men, who ought not to fire till the enemy are on the glacis. They should be provided with

with grenades to throw in the midst of the enemy who have jumped into the ditch, may even ashes or quicklime, whose burning dust cannot fail to blind the enemy, should be had if possible. If the strength of your detachment will admit of it, eight or ten soldiers should be placed in the ditch (on the opposite side from the enemy), so divided as to take the enemy on the flanks, who have jumped into the ditch. This kind of sally, by running round upon the right and left at the same time, must astonish an enemy who could not dream of being attacked.

If there are heights from whence the enemy can crush your people with stones, they must be occupied with eight or ten men covered with a breast-work, to prevent the enemy from possessing them, or guard against them, as has been formerly directed.

In the defence of houses, mills, &c. as well as regular fortifications, the men should be made acquainted with the different manœuvres they may employ for their defence; without which they do not foresee the intentions of their officer, and may counteract one another by their being in disorder.

The obstinate defence of a post is the action where an officer detached singly can acquire the greatest glory; the resistance not proceeding from the number of soldiers destined to defend it, but from the talents of the officer who commands. It is in him that the strength of the intrenchment lies; and if he joins to determined bravery the abilities necessary on these occasions, and can persuade his soldiers that the lot the enemy prepares for them is a thousand times worse than death, he may be said in some sort to have rendered his post impregnable.

When an officer who is posted in a redoubt is attacked by the enemy, he needs not to be employed in firing himself, but in seeing that the soldiers do their duty, and do not throw away their fire in the air. If he sees their ardour slacken in the rage of the attack, he must encourage them; if he sees the enemy making greater progress on one side than the other, he must weaken one to support the other: this movement may be dangerous, and it were better to have a small reserve in case of need; but an officer with a small detachment that can scarcely line in the parapet, cannot spare men for a reserve, but must employ every means they have been preparing for their defence, as directed above.

In the defence of detached buildings, there are so many different retreats, that it becomes an arduous task to succeed in an attack, when brave people are to defend them. They have the loop-holes on the ground floor to defend, when beat from the intrenchments without, and may resist great numbers, by retiring gradually to the different floors of the house, where they should have large buckets of water provided to throw upon the enemy, which, though it may appear trifling, is one of the most disagreeable that can be opposed to the assailants; for at the same time that it wets their powder, arms, and cloaths, it hinders them from seeing what is doing above, prevents every scheme for setting fire to the house, and may oblige them to desist from the attack.

The Chevalier Folard in 1705 had a small country-house near Brescia to defend with four companies of

grenadiers, against the chosen troops of Prince Eugene's army, who were obliged to retire after penetrating into the court.

The prince of Wirtemberg, says Monsieur Folard, believing that there were succours coming to us, imagined that if he could get possession of a pigeon-house, from whence a very hot fire was kept up, the post would soon surrender: he therefore caused it to be attacked; and our soldiers having taken away the door to light a fire within, the officer who commanded below being wounded, and not able to resist the firing which was levelled through the door-way, was made prisoner. There were seven grenadiers on the top of the pigeon-house, who were summoned to surrender, but who thought themselves too well posted to submit so soon: they therefore replied that they would not yield till the pears were ripe, as they were capable enough of holding their post; and accordingly kept a constant fire upon the enemy, till the prince of Wirtemberg retired, and left the place covered with dead.

Having formerly observed that the defence of a post does not depend upon the soldiers who are destined for that service, but upon the officer who commands, the following example may serve to confirm the observation, and will at the same time show the utility of having stones collected to throw over upon the enemy, as formerly recommended.

In the month of September 1761, captain-lieutenant Alexander Campbell of the 88th regiment, with 100 men under his command, was pitched on to defend the remarkable post near Cassel in Hesse, called the *Hercules*. Monsieur Roziere the celebrated partizan and engineer of Marshal Broglie's army, with 600 infantry and four squadrons of cavalry, arrived in the neighbourhood of the post the morning of the 22d; and having beat a parley, surrounded and carried off the two men who were sent out to receive the message. After having examined them separately, he caused a detachment, under cover of his musquetry from a hill that was opposite to the principal passage, to advance and mount the stair, three men abreast; which they did so slowly and without any interruption, that the whole stair of about 100 steps was full of men, when Captain Campbell (who had made an excellent disposition for the defence of all the parts of his post), having some chosen men at each side of him, waited to receive those who advanced first upon their bayonets, and firing at the same time, gave the signal for the rest to throw over large stones which he had collected and disposed for that purpose; which made such havoc, that Monsieur Roziere, startled at the unexpected reception, and despairing of success, wished to get his party off. Captain Campbell seeing the destruction of the enemy without a man of his being hurt, and that he could renew the reception as often as they choose to repeat the attempt, was elated with his success and encouraging his men, when he happened to move from the wall that covered him, and received a musket shot from the opposite hill, which entered a little below the left temple and came out at the same distance below the right; upon which he fell, and the party beat the chamade and surrendered. After two hours possession the French retired, carrying off the prisoners, and leaving Captain Campbell, whom they thought

thought dead, to be saved by our troops, who soon took possession again, and sent him to be recovered, and to display new merits in his profession.

Vegétius very particularly recommends the collecting of stones to throw over the walls, and it is certain that nothing better can be done against an escalade; though they should have some long forked sticks to pass through the loop-holes and overset the ladders, while they shower down tiles, slates, stones, ashes, and lime, as well as the rafters from above.

If the enemy take cannon to force the post, it does not appear how it can be resisted, unless the house is low, and they cannot range round the entrenchments, as every shot can make a large opening in bad built houses, and may crush the besieged. The only means then to shun being massacred is to capitulate, or to rush out briskly upon the enemy when they least expect it. The first is not resolved upon but when the honours of war can be obtained, which is to march out with drums beating to return to the army with a proper escort. But if this capitulation cannot be obtained, the besieged having nothing left consistent with true bravery, but to rush out sword in hand, and cut their way through the enemy. The necessity of conquering changes the brave man into the determined soldier, which gives him the means of retiring to the army or some neighbouring post.

It was by a manœuvre of this kind that Marshal Saxe saved himself at Chrachnitz, a village in Poland, where a party of 800 horse had a design to carry him off with 10 men that were his attendants. The marshal, after having resisted a long time in the chambers of the inn where he was, and seeing he could hold out no longer, rushed out upon them in the night sword in hand, fell upon one of the guard who did not expect it, run him through the body, and retired to Sandomir where he had a Saxon garrison.

If a post is to be abandoned when it can be no longer held, and you are going to make the fall, you should continue to fire with spirit, taking away barricades from the door through which you are to pass with as little noise as possible. When they are assembled, the whole party should go out close together, rushing with their bayonets to the place the officer thinks the least guarded. You ought never, says Mr Polard, to wait for day to execute these sallies, which cannot succeed but in a dark night, by which you easily conceal from the enemy the road you have taken; for which reason you should not fire, but open to yourselves a passage sword in hand, lest the enemy come where they hear the noise.

The Baron de Travers says, that not to be met by the enemy we should take the contrary way to that he expects us to take, and which it appears we ought to take: a small party can hide themselves every where, and as it is not common to search places on the enemy's side, there they are most secure, and may pass the day, to take another road under favour of the night.

Officers should be attentive to distinguish between the true and false attacks, and not despair when beat from their first entrenchments. The defence of posts is so easy, that it is surprising they do not hold out longer than they commonly do. There wants only resolution and vigilance, taking every advantage of the ground, and persuading the soldiers that nothing but

the most manifest baseness can let the enemy penetrate. The example of Cremona, surprised by Prince Eugene in 1702, will remain a proof to posterity of what determined bravery can do; and show, that though an enemy is master of half the ramparts, and part of the town, he is not master of the whole.

Prince Eugene having formed the design of surprising this town, which was defended by a garrison of French and Irish, got some thousand Austrian soldiers admitted at a secret passage by a priest. These troops seized the two gates, and a great part of the town; the garrison buried in sleep were waked by the assault, and obliged to fight in their shirts; but by the excellent manœuvres of the officers, and resolute bravery of the men, they repulsed the Imperialists from square to square, from street to street, and obliged Prince Eugene to abandon the part of the town and ramparts of which he had been in possession.

What then can be the reason they do not defend posts and villages as well now-a-days, especially when they have secured a retreat fit for making a good defence, or obtaining an honourable capitulation? It seems to proceed from their not applying enough to know the causes of the misfortunes they fall into, and being unacquainted with what has happened to those who have gone before. The people who attack have nothing supernatural in them, and are not different from those who are attacked.

Posts have often resisted the first and greatest efforts of the assailants, and have yielded or been abandoned to subsequent attacks, though much less spirited. How comes this? It is owing to an officer's not daring to abandon his post at the first attack: he repulses the enemy, because if forced they will be put to the sword with their whole party; but when the enemy comes back, he thinks he has nothing to reproach himself with, having defended it for some time, so retires, or surrenders. Since he could repulse the enemy when in good order and quite fresh, how much more easy and less to be dreaded when they return harried with fatigue?

Is not the great cause of misconduct among military men the want of encouragement to excite emulation? An officer who is not protected, who is never sure of the least favour, neglects himself, and takes less trouble to acquire glory, rarely heard of, though merited by the bravest actions, than to enjoy the tranquillity of an ordinary reputation.

It is not expected that an officer who is placed in a post should seek to engage; but that he should steadily resist when he is pressed, and die rather than abandon his entrenchment.

Historians have been very silent about posts being well defended; though the lessons to be drawn from them may be more generally instructive, and as agreeable to read, as those left us of the best fortified places of a state. We are astonished at the account of 100,000 men perishing before Ostend in 1604, and their general, the Archduke Albert, with the ruins of his army, not making himself master of it, till after a three years siege: nor is our wonder less, to see Charles the XII of Sweden, in the year 1713, with seven or eight officers and some domestics, defend himself in a house of wood near Bender, against 20,000 Turks and Tartars.

Several historians mention the defence of this house because it was done by a crowned head; but brave actions, whoever are the authors, should never be buried in oblivion, as they excite emulation, and are full of instruction.

SECT. VII. *Of the Attack of Posts.*

ALTHOUGH the taking of a post is always difficult when you have to do with people who know how to defend it, nevertheless you may succeed in attacking them by surprise and stratagem. We ought never to form a scheme for an attack upon simple speculation, because from reasoning we often think things are feasible, which we find impossible in the execution. When you intend to undertake an action of this kind, you ought to form a just idea of it, by examining all the branches separately, and the different means you can use, so that, by comparing them together, you may see if they concur, and answer to the general purpose; and lastly, you are to take such measures as may in a manner render you certain of success before you begin.

As it is not the practice of the army to choose a particular officer for the attack of an entrenched post if he does not offer himself, so an officer should not embark in such an enterprise, without having examined the means of succeeding, and being capable of showing the general a plan of what he has projected, to see if he will consent to the execution of it. If the general approves the plan, he must beg leave to go to reconnoitre the post with a man or two, that he may take his measures more justly for the execution of it.

When he has been to reconnoitre, as is directed in a former section, and has got every necessary information, he should go to give the general an account of his discoveries, and receive his last orders for the attack, for the soldiers of his party, and for those who are to march to sustain him.

The choice of men that are to go upon the attack of a post, is so much the more essential, as the success of the enterprise depends on it. None but volunteers of determined bravery ought to be taken, men who are not stupid, and have no colds upon them; because he who does not attend to the orders of his officer, runs on with blind zeal; and he who coughs or spits, may discover the party to the enemy's sentries, and cause the best concerted scheme to fail. As to those who are to support them, they may be taken according to their rank in the guard or detachment, as the general judges proper.

The disposition for an attack must depend on the discoveries that are made, so as not to be obliged to return in the midst of the execution. The men being chosen, they must be inspected, to see that nothing is wanted which can contribute to their success; because, if the post is fortified with an entrenchment of earth or fascines, the two first ranks should be provided with spades and pick-axes beside their arms; if fraised or palisadoed, they must likewise have hatchets; and if covered with masonry, they must have ladders.

The men should be in their waistcoats, to be less constrained. If they propose to make one or two true, and as many false attacks, so many platoons must be formed of the chosen party, as they are to

make true ones, and the sustaining party to make the false attacks, so as to divide the enemy and share their fire. A man must be placed at the head of each platoon, who is capable of commanding them, and, if possible, the same who had been employed before to make discoveries, as he may more easily guide the division. The orders which should be given to those leaders, are to march together to the place where they are to separate, and then each to go to the spot which is appointed for them, in the neighbourhood of the post, and wait there, with their bellies on the ground, for the signal to jump into the ditch and scale the post.

If you are to be conducted by spies or guides, they should be examined about every thing that can be of use, before they are employed, especially about the road by which they propose to conduct you. The reason of this is, because we often see simple people, animated with the hope of gain, imagine they can easily lead a party, when they have only a great deal of good-will; but if you find in those who offer all the necessary qualities, you must immediately secure them to you as much as possible, by making them dread the destruction of their houses, and pillaging their goods, if they lead the party into a snare; you may likewise ask their wives and children as pledges of their fidelity, and, the moment of setting out, place them between the corporals of the first rank, tied with a small chain; which precaution is the more essential, as traitors have often been known, on pretence of conducting a party to seize a post, to have led them where they have had their throats cut in the middle of the night, and have disappeared at the very moment of its execution. If you make your guides hope for a recompence proportioned to their services on one side, on the other you must make them fear the cruellest punishment if they do amiss.

The night being the most proper time to march to the attack of a post, you should set out soon enough to be ready to make the attack an hour or two before day. Care must be taken that it is not moon-light when you propose making the attack; the soldiers ought to march two and two, with the least noise possible, especially when passing between the enemy's sentries: you must likewise recommend to them, neither to speak, spit, or smoke. The detachments must get as opposite as possible to the salient angles of the entrenchment, as it is probable that they will be the least defended by the enemy's musketry. If a patrolle of the enemy comes while you are on your march, or ambushed in the environs, you need not be alarmed, nor make the least motion which may make the enterprise fail, but remain concealed in the profoundest silence, that the patrolles may pass without perceiving any thing, and afterwards pursue your design.

If the post which you want to carry is a redoubt with a dry ditch and parapet of earth, your two first ranks must have spades and pick-axes, with their arms slung, and, on the signal being given, jump into the ditch together; because it ought to be a general maxim in attacking a post, to strike all at once. When the first rank have jumped down, the second must stop a moment, that they may not fall upon the shoulders or bayonets of the first. The two first ranks having got into the ditch, they should immediately run to sap the angles of the scarp and the

parapet of the redoubt, to facilitate the mounting of the rest of the party; the leaders of each division should observe at the same time, that the soldiers who remain armed with their firelocks, and who have likewise leaped into the ditch, do not interrupt those who are demolishing the scarp of the redoubt, but protect them by presenting their bayonets to the right and left, and be ready to repulse any of the enemy that happen to be placed in the ditch.

If the parapet is raised, they should break as many of the fraises with hatchets as is necessary to let the men pass. When the breach is made, the workers should drop their working tools; and taking their arms from the slings, mount up with fixed bayonets, and rush upon the enemy huzzaing.

When you march to attack a redoubt or such post, where the enemy have a connection with more considerable posts, the commanding officer should charge on that side, so as to cut off the communication. People who see themselves briskly attacked without hope of succour or retreat, will very soon beg for quarter.

When the scarps and parapets are of stone, they can only be carried by scaling; but you may succeed by being brisk in surrounding and sustaining the attack. An officer who is to attack a post of this kind, should take care that his ladders are rather too long than too short, and to give them in charge only to the stoutest of the detachment. The soldiers should carry these ladders with the left arm passed through the second step, taking care to hold them upright at their sides, and very short below, that they may not dislocate their shoulders in leaping into the ditch.

The first ranks of each division provided with ladders, should set out with the rest at the signal, marching resolutely with their firelocks slung at their backs to jump into the ditch. When they are arrived, they should apply their ladders against the parapet, observing to place them towards the salient angles rather than the middle of the curtain, because the enemy have less force there. They must take care to place the ladders within a foot of each other, and not to give them too much nor too little slope, that they may not be overturned or broken with the weight of soldiers mounting upon them.

The ladders being applied, they who have carried them, and they who come after, should mount up and rush upon the enemy sword in hand. If he who goes first happens to be overturned, the next should take care not to be drawn down by his comrade; but on the contrary, help him to pass between two ladders, and immediately mount himself, so as not to give the enemy time to load his piece.

As the soldiers who mount the first may be easily tumbled over, and their fall may cause the attack to fail, it would perhaps be right to protect their breasts with the fore-arms of light cuirasses; because if they can penetrate, the rest may easily follow.

The success of an attack by scaling is infallible, if they mount the four sides at once, and take care to shower a number of grenades among the enemy, especially when supported by some grenadiers and piquets, who share the attention and fire of the enemy.

During the siege of Cassel, under the Count de la Lippe, in the campaign of 1762, a young engineer undertook to carry one of the outworks with a much

smaller detachment than one which had been repulsed; and succeeded with ease, from the use of grenades; which is a proof that grenades ought not to be neglected, either in the attack or defence of posts.

If the ditch of a post is filled with water, and but middle-deep, that should not hinder you from jumping into the ditch to attack, in the manner that has been mentioned; but if there is a greater quantity, and you cannot pass, the soldiers of each platoon should carry fascines, or faggots of small branches well bound, and made as large as possible, to fill up the ditch, and make a kind of ford, so as to get at the parapet, either to demolish or scale it.

Many ways of filling up the ditch, recommended by different authors, might be mentioned; but the fascines are preferable to them all, as the soldiers can easily carry them before them, march quicker, and make use of them as a defence against musketry, and, reaching them from hand to hand, soon make a ford.

If the approaches of the post are defended by chevaux de frise, the first and second rank of each platoon must break them down with hatchets; or with iron grapplings tied to ropes, they may pull them to them, and separate them. If it is a breast-work of felled trees, you must have fascines thrown against the points, or upon the branches, upon which the soldiers can easily pass. If there are two or three rows, you may burn them with dry fascines lighted at one end, and thrown in the middle row. In case of trying this last scheme, the soldiers must retire to a little distance after throwing the fascines, that the enemy may not see to fire at them by the light of the fire, but place themselves so that they can fire upon any who may attempt to extinguish it. If there are chausse-traps, they must be swept away, by dragging a tree or two over the ground where they are scattered.

In the attack of detached buildings, you must seize the approaches, and strive to scale them; to get on the top, and crush the people who are below, with the tiles or slates; but if the enemy has uncovered the house, you must throw as many grenades as you can in at the windows and doors; or dry fascines, with lighted faggots dipped in rosin; or fire-balls, to endeavour to set fire to them, and smoke them out. If the weather is windy, you should profit by it to set fire to the house, and try to shut up the loop-holes which the enemy have pierced near the ground, with bags of earth, so as to sap the corners. If you have some cannon, you may shorten the ceremony, by planting them against the angles of the post. If you have none, you may successfully suspend a large beam by a rope, to three bars placed in a triangle, in imitation of the Roman battering ram: this beam pushed violently against the walls, will soon make a breach; but you must observe, in suspending it, to do it in a dark night, so that the enemy cannot prevent it by firing at the soldiers who are employed in the work. If it is glorious to get out with honour on such an attack, it is no less so, to make it so as to cost but few people. The blood of the soldiers is precious, and cannot be too much prized, and an able chief will neglect no means that can contribute to their preservation. The comparing of two examples will show the importance of what is advanced.

During the two sieges of Barcelona, by Monsieur de

de Vendome in 1697, and Monsieur de Berwick in 1713. The first of these generals caused the convent of Capuchins, situated out of the place, to be attacked sword in hand by several detachments of infantry, and carried it in three hours, with the loss of 1700 men. Marshal Berwick caused the same convent to be attacked in the year 1713. They were equally entrenched, and reckoning to make him pay as dear as Monsieur de Vendome had done; but this general having opened a fort of trench before the convent, they not expecting to be attacked in form, surrendered at discretion, after having held it 24 hours. The reader is left to judge which example to follow.

You should prepare for the attack of a village, or such like post of large extent, as has been directed in the section for detached posts: but as these fort of attacks are always more difficult than others, on account of the multiplicity of schemes they have to encounter at every step, an officer should not march there till he is acquainted with the strength of the entrenchments; the situation of the smaller posts; the obstacles to be met with in every street or square; and even what terms the inhabitants are on with the soldiers of the garrison.

If an officer takes his information from country people, he should inquire in such a seemingly careless manner, that they may not discover his design to the enemy, and they take measures to prevent them: he must likewise endeavour to be well assured of the reports of the peasants, by comparing them with those of the deserters, and with what he has discovered himself. When he is well informed of the situation of the enemy, he should then make his dispositions for the attack, and observe to mention to those who are to command the different platoons, all that they ought to do, either in real or false attacks. The real attacks should be made in places that appear inaccessible, because the enemy, trusting to the difficulty of access, are always less guarded there. He may likewise attack the houses situated at the entrance of streets, because when they are once gained, it is easy to pierce the walls that separate the houses, from whence they can easily crush the enemy with stones, and force them to fly to their last entrenchment.

In an enemy's country whom you would not spare, it is easy, by setting fire to the four corners of the village, to force the besieged to surrender; but, besides its being inhuman to use means which tend to the devastation of a country, it is very dangerous to drive the inhabitants to despair, because they then fly into the woods, gather in parties, scatter themselves every where, murder the soldiers who stray, assassinate the sutlers, hinder every peasant from carrying provisions to camp, and may destroy an army.

While the assailants have penetrated into the village, the commanders of each division ought to take care to leave small detachments at all the churches and squares they find; to stand firm and sustain the main body in case they are repulsed. You must watch very carefully that the soldiers do not withdraw to pillage the houses of the inhabitants, as whole detachments have been driven from towns and villages where they had penetrated, from having neglected this precaution.

Three days after the surprise of Cremona in 1702, some Germans were found in the cellars, where they

had got drunk, and were astonished when they were told that they must quit these agreeable retreats. An officer who would shun a disorder so fatal, should forbid his soldiers to stir from his party on pain of death; and by placing a sentinal in the rear of each division, take care that no one falls behind.

If you find cavalry drawn up in the squares or open places, the assailants should remain firm at the entrance of the streets that meet there, while some go up to the houses that are at the corners, and fire upon them from the windows: if this causes any disorder among them, they should be charged with fixed bayonets to make them surrender. If the interior part of the village is defended with cannon, you should march quickly to the place where they are, and take them, or nail them up, or turn them against the enemy or principal post of the village.

Polybius, in his seventh book, gives an account of an attack full of instruction for military men. The blockade of Sardis by Antiochus the Great, had lasted two years, when Lagoras of Crete, a man of extensive knowledge in war, put an end to it in the following manner. He considered that the strongest places are often taken with the greatest ease, from the negligence of the besieged, who, trusting to the natural or artificial fortifications of their town, are at no pains to guard it. He knew likewise that towns are often taken at the strongest places, from their being persuaded that the enemy will not attempt to attack them there. Upon these considerations, though he knew that Sardis was looked on as a place that could not be taken by assault, and that hunger only could make them open their gates, yet he hoped to succeed. The greatness of the difficulties only increased his zeal to contrive a means of carrying the town.

Having perceived that a part of the wall which joined the citadel to the town was not guarded, he formed the design of surprising it at that place: he observed that this wall was built on the top of a rock which was extremely high and steep, at the foot of which, as into an abyss, the people of the town threw down the carcases or their dead horses and other heaps of burden; at which place great numbers of vultures and other carnivorous birds assembled daily to feed; and after having filled themselves, they never failed to rest upon the top of the rock or wall, which made our Cretan imagine that this place was neglected, and without any guard upon it.

On this thought, he went to the place at night, and examined with care how he could approach it, and where he ought to place his ladders. Having found a proper place for his purpose, he acquainted the king with his discovery and design; and the king, delighted with the project, advised Lagoras to pursue it, and granted him two other officers whom he asked for, and who appeared to him to have all the necessary qualities for assisting him in his scheme.

The three having consulted together, they only waited one night, at the end of which there was no moon; which being come, they chose 15 of the stoutest and bravest men of the army to carry the ladders, to scale the walls, and run the same risk that they did. They likewise took 30 others to place in ambush in the ditch, and to assist those who scaled the wall to break down a gate into which they were to enter.

Petite
Guerre.

The king was to make 2000 men follow them, and favour the enterprise by marching the rest of the army to the opposite side of the town. Every thing being prepared for the execution, Lagoras and his people approached softly with their ladders; and having scaled the rock, they came to the gate which was near them, and having broke it, let in the 2000 men, who cut the throats of all they met, and set fire to the houses, so that the town was pillaged and ruined in an instant.

Young officers who read this account, ought to reflect on this attack. The attention of Lagoras, who went himself to examine the places proper for fixing the ladders; his discernment in the choice of the officers and soldiers who were to support him; and the harmony of the whole means that were employed on the occasion, afford very excellent lessons for any officer who may attempt such an attack.

SECT. VIII. *Of Surprises and Stratagems for seizing Posts.*

All the environs that have any relation to the place the enemy occupies must be known; on what side lie the avenues, morasses, rivers, bridges, heights, woods, and all covered places that are in the neighbourhood, without which it is scarce possible to regulate approaches prudently. It is equally necessary to know nearly the number and kind of troops with which he possesses the post, that you may not attack him with insufficient force. It is likewise necessary to know if the enemy is careful or remiss in carrying on his duty. The knowledge of these circumstances contributes infinitely to form a project of surprise well, and to conduct the whole expertly.

As to the manner of surprising a post, it is impossible to establish certain rules on the subject; because, among a thousand means which chance offers, there are rarely two alike. The quickness of a concealed march upon a distant post negligently guarded; a thick fog which prevents being seen; a river where there is a ford the enemy is ignorant of; an aqueduct; a subterranean passage; a hollow road which is not guarded; a frozen rivulet; a blocked up passage; a secret correspondence; a fair or market day, and disguises of every kind, are the different stratagems that may be used as occasion offers, and by which we may promise ourselves success though they have been frequently employed.

It must be observed, that there are stratagems with which it is impossible to succeed without a proper force to sustain them. A town or village, for example, where we are introduced by a secret correspondence, cannot be carried without being well seconded. The only means of managing the surprise of posts well, is to have for a maxim to divide your force instantly, to seize the castle, church, church-yard, or public squares. It has been said, that troops so divided can act but weakly, and run a risk of being defeated separately. But by making as many detachments as the enemy has posts, in the dismay caused by surprise, it is easy to carry these posts before they who defend them have time to dispute them or even look round them. The enemy being likewise obliged to divide, and not knowing what side to prefer, there is almost a moral certainty, that, surprised with the noise which they hear

all round, they are ready to let their arms drop out of their hands: beside, the horrors of a dark night, and the dread that cannot fail to seize a party who are surprised, represent objects much greater than what they are, so that they imagine they have to do with a whole army.

The bad success of the affair at Cremona makes nothing against this opinion. If instead of stopping to make prisoners, a detachment had gone directly to the citadel, which should be the way in all these kind of actions, it would have been impossible for these brave officers who drove out the Imperialists, to have made so glorious a defence.

M. de Schöwer did otherwise when he surprised Benevar in Spain in 1708, and did not fail. He learnt that the Spaniards neglected the guard of an old castle which was at the entrance of the place; and marching in the night he took it, and detached several parties to attack the town. Surprised with such a visit, they sought for safety in flight, and ran to take shelter in the citadel, but were scarcely entered when they were made prisoners. The enemy did not think of the attack being begun where they were strongest; but it is the best way, as it is to be presumed they have divided their forces to be able to defend every where.

M. Menard, in his history of Nîmes, gives an account of the surprise of that town, which merits our attention. Nicholas Calviere, called captain St Cosme, having resolved to make himself master of this place, engaged a miller whose mill was situated within the walls, at the side of the gate, to file the bars of a grate which shut up the entry of an aqueduct through which the water passed into the town, for several nights to put wax on the filed places to conceal them in the day, and to receive 100 men armed into his mill, while a considerable body of cavalry and infantry should arrive from different places to sustain the enterprise.

The day for the execution of his project being fixed for the 16th of November 1569, and proper orders given for the rendezvous of the troops, St Cosme came out of the mill with his party at three o'clock in the morning, and advancing to the guard at the gate, put them to the sword, and opening the gate let in 200 horsemen, with each a foot soldier behind him. These troops having entered the town, formed several detachments immediately: one of which went to block up the citadel; while the rest, scattering over the squares of the place, and sounding their trumpets instantly, made themselves masters of the town.

There are a number of circumstances mentioned in this surprise, which convey a great deal of useful instruction. Captain St Cosme knew how to profit by the negligence of the governor, who omitted to guard the entrance of the aqueduct; to make a proper choice of cavalry for advancing so readily with the infantry from different quarters; the justness of the orders given the troops, which brought them 15 leagues from Nîmes at the hour and place appointed for the rendezvous; the precaution with which he invested the citadel, to prevent his having to do with the garrison in the streets; his attention in dividing his troops into the different quarters of the town, and making them sound their trumpets, that the inhabitants might imagine they were very numerous.

There

Petite
Guerre.

There are instances of surprises succeeding from singular address. Captain Brachis, wanting to make himself master of a tower in the territory of Amberla, caused one of his soldiers to disguise himself like a woman, and gave him a basket in his hand with a sickle. This man so disguised ran as fast as he could to the tower, pretending to have fled from a party of the enemy: the guard let him enter and mount a ladder to the top of the tower to show the sentry where the enemy was; but he was scarcely got up, when he clove the sentry's head with the sickle, seized his arms, and obliged those who were below to abandon the post.

The active corps of the partisan, without trusting to the stratagems that others have succeeded by, must find other resources than those against which people are so prepared now-a-days; and as the surprising of the enemy is the great business of the partisan in carrying on the *Petite Guerre*, he must see what can be effected by his hardiness and activity.

The expedient which appears to be the most proper for an officer who has 400 infantry under his command, and is certain that the garrison is only 200, (for surprises should be always attempted with a double force) is to choose very bad weather; the strong winds, for example, and fogs in winter; or the storms and tempests in summer, when, after excessive heats, violent winds rise suddenly, and agitate the air.

When you have meditated such a scheme, then is the time to put a part of your infantry in covered waggon, which should be kept ready for the purpose. The whole party ought to be provided with dog-skin covers for their gun-locks and cartouch-boxes, to take off readily when there is occasion; and the rest of the infantry to be mounted behind part of the cavalry. Both parties to assemble at some place a league distant from that which you would surprise, and there to stop; when, if you see the bad weather dissipating, you must retire till another occasion. If you renew it ten times, you need not despair; a strong place deserves this trouble; the blow is too honourable and too important to lose courage, and success will overpay every fatigue.

But on the contrary, if the storm forms, and the wind increases, direct your approaches in such a manner, that you may always have the wind on your back; because if you have it in your face, the enemy's sentries can look forward and discover you; and likewise if it is in your face, your horses cannot be made to advance without a great deal of trouble. These precautions being taken, you advance more quickly as the storm increases, the horses and waggon going with great speed before the wind. You need be in no uneasiness about the enemy's sentries seeing you, or hearing the noise of your march; because the severity of the weather obliges them to enter their boxes, and turn their backs to the wind, to save their eyes from the dust and sharpness of the air.

At 300 paces from the place, the foot and part of the cavalry should dismount and fix their bayonets, the rest of the cavalry to remain with the waggon near some trees or houses, the waggon turned for a retreat. Divide your infantry into five detachments, and instantly run at a great rate, keeping your men as

close as possible, and passing the barrier and gates, seize all the sentries and the guard without firing or making the least noise, which may be executed with an extreme quickness, to be acquired by practice. While the first detachment seizes the gate and all the sentries of its environs, the rest must run rapidly into the town. One must go quickly to seize the main guard; another to seize the governor or commanding officer; the fourth, which should be the strongest, should fly to the caserns or mens barracks, to seize their arms; the fifth to remain in the street near the gate for a corps de reserve.

Every detachment must be conducted by prisoners made at entering; and orders sent with all speed, to cause half the cavalry to advance and patrol the streets, as the infantry get forward.

As this kind of surprise can succeed only under favour of a storm, which rarely continues any time, it is evident that the march and execution must be conducted with inexpressible swiftness, and the orders be perfectly understood. It is true, that rain is inconvenient for the infantry, whose feet slip on clay-ground; but they must do their best, and frequently it is found that the roads which are most used are not therefore the most slippery.

If it happens that you are perceived in taking possession of the gate, and they take the alarm, you must quickly divide your party into two wings, mounting them on the rampart, the one to the right, the other to the left; and seizing the loaded cannon, turn them upon the town; and at the same time summon the garrison to surrender. If you happen to fail, and are obliged to retire, you do not risk much, as they will not care to molest your retreat.

There may be a reluctance in attempting such a surprise; it may appear to be hazardous and rash, and a conduct too nice not to despair of success: but Mr Jeney says that experience convinces him of the validity of the means proposed, and relates what happened to him upon two occasions, to prove that the cold east winds or storms are the most proper times for attempting surprises.

Being at the head of 30 hussars, says he, and willing to shun a storm which was gathering behind us, I pushed to get to a place which was well fortified and occupied by a numerous garrison: the wind was strong, and I passed the barrier and all the gates with my horses, which made a great noise, without any sentry either seeing or hearing; and though I called to the first guard to declare myself, no one perceived me. I crossed the whole town without seeing a soul in the street; and hurrying to an inn in the other suburbs, I went out at the gallop, and saw only the sentry at the last barrier, to whom I answered without our comprehending one another; nevertheless the rain had not begun to fall, but the wind was violent. I experienced the same during the winter, when the east wind was very proper to facilitate the surprise of a fortified town or post. On Christmas night 1757, I passed through the country of Hanover with 80 horse between two guards of the enemy without being perceived. I marched over the middle of a plain when the night was clear, with a violent east wind, which prevented any sentry from turning his head to look.

look at me, and I went quietly to carry off horses in the rear of their army. The following night at my return, I passed two different posts of our army; the one guarded by a party of hussars, the other by a regiment of dragoons, without being seen but by one sentry in the middle of the dragon post, who durst not challenge, because it was no longer time, having passed the first guards.

You may likewise take the advantage of bad weather to scale all sorts of posts surrounded with walls, as towns, abbeys, castles, &c. to do which, you must approach in the dark, and seize the moment of a great squall, or when a cold east wind obliges the garrison to take shelter from the rigour of the season: then there is no one upon the ramparts, and the sentries turn their back to the wind, or remain in their boxes, while your people are warm with marching, and animated with the hopes of success. You need not be apprehensive of the enemy seeing you if you advance on the side next the wind to place your ladders, because the sentries will cover their faces, and bend down their heads to save them from cold.

The time of a thick fog is not less favourable for approaching and forcing an entrenched post. When the fog is low, the infantry should creep on all fours, the better to conceal them from the enemy's sentries. These sort of surprises are the least dangerous, you run scarcely any risk; but if you cause some false attacks, the garrison will not fail to run to arms, and sometimes make you pay dear for failing.

When you would surprise the enemy in a village, farm, monastery, or some place detached from the army, you should divide your party into two bodies, each composed of cavalry and infantry; the one to take the enemy in the rear, the other in front, taking care to cause some waggons to follow, which may carry off the wounded in case of need. You must calculate exactly the time it will take the first detachment to go round the enemy. The two commanders should agree on a word for rallying, and the time of making the attack, which should be in the night, especially if the post is so distant from the army that they can receive no assistance; for in that case the time is favourable till day-break. They must regulate their departure according to the distance they have to go; and the detachment which goes round the enemy, ought to take no more infantry than can be carried behind the horsemen. This detachment having got round, should form about a quarter of a league from the post, and 100 paces out of the road.

When the other detachment has arrived within a quarter of a league of the post, your cavalry should form out of the road with the waggons and drums near them, who are not to advance till ten minutes after the departure of the infantry, who must advance towards the fires of the enemy, stopping as much as possible. They must take care to conceal themselves from patrols, as has been directed; and when they see them passed or entered the post, the infantry must hurry on to gain the village, and clear the entry by which the cavalry must pass, in case it has been barricaded with waggons. You must run rapidly to the place where you see the fires lighted, and make as many detachments as you see fires, in order to surprise the whole at once.

The cavalry who followed slowly, must instantly join to the noise of your arms and cries their trumpets and drums, advancing with all speed, and leaving only a non-commissioned officer with some horsemen near the waggons. The detachment, which is advanced on the other side of the village to turn the enemy, on hearing the alarm, must immediately advance, sounding trumpets, beating drums, and attacking all who would save themselves on that side. You may rely on it as certain, that the enemy, seeing all his guards surrounded by your infantry scattered in the village, and hearing the march of different bodies of foot and horse who arrive on all sides, will not delay to surrender, or seek to save himself by a disorderly flight; it will be easy then for your cavalry to fall upon the flying, and stop them. The party should be forbid to pursue the enemy more than a quarter of a league in the night; but no pursuit at all should be attempted, if it is in an inclosed country.

The post being taken, the booty and prisoners should be sent off immediately under the care of the infantry, putting the wounded in waggons, or on the horses that are taken, the cavalry making both the front and rear-guard, and taking care to have the last the strongest. When the enemy's post is ten leagues or more distant from yours, it is certain that they will have less distrust, and be more easily surprised. In that case the infantry, with a lieutenant and 20 horsemen, should stop at half way, concealed in a wood or farm, keeping constant guard.

The commanding officer should leave this place at the head of the rest of the cavalry; and if he finds that he cannot arrive that night, he must cause them to carry refreshments. He must likewise take an intelligent guide from thence, to whom he must not communicate his design, till they have gone some way on the road towards the enemy. He must accompany his declaration with promises and threats, assuring him that he will generously reward his zeal and fidelity; but will kill him or set his village on fire if he attempts to deceive or run away.

At some little distance from the place, you must quit the road on the right or left, and be conducted to another, which leads to some height the most convenient for passing a league on one side of the enemy's post. In bad winter weather you need not keep at such a distance, because there is less risk of meeting any one in the country.

When you get as far as the post, you must move obliquely to the road which leads from the enemy's army, and by which you must advance to attack the post. If it happens, that for want of roads the guide must conduct you over fields and meadows, it is of little consequence, provided that the route is conformable to the design.

A genius for war has sometimes pushed boldness so far, as to surprise the wings of an army, encamped in a level country, on a plain uncovered on all sides. This sort of surprise is a temerity that is scarce to be imitated. The danger is great; and the retreat of so small a corps as that of a partisan, runs always the risk of a total defeat, unless it happens in the middle of a dark night, which can conceal your approach or your flight; but it likewise exposes you to take some very dangerous steps in the dark; to wander from your route, and

and to disperse your people: for which reasons such attempts are never advisable,

The case is very different when the enemy's camp extends into a mountainous country, covered with woods to secure your retreat; for then, with the assistance of a good guide gained by money or promises, you may be conducted in the night into woods, and secure your approaches by gullies and bye-ways.

You must take great care, in coming out of the wood, that you do not come upon some post in the front of the wing you want to surprise; because, in that case, you must leave a detachment of infantry at the passage. While your cavalry advance to get round their advanced post, another detachment of cavalry and infantry must place themselves opposite to the flanks of the post. You must then fall briskly upon the wing of the camp with cavalry alone, and at the same instant the detachment left on the flanks must attack the post with the infantry flooping as they advance; and in the attack, both should let up a most frightful cry to alarm the whole army.

As it is certain that the piquet of the army will not delay to run to their assistance, you must instantly seize and carry off whomsoever you meet, officers, soldiers, or their horses, and every thing you can take away, making haste to regain the passage. The cavalry should go first with the booty and prisoners, the infantry making the rear-guard till they are out of the wood, and then take the front. You must endeavour to make at least half the retreat that night, and before that the enemy does not follow you in the night, lest you be taken in flank.

There is no time more precious for a partisan, or that merits so much attention, as that of a battle, when every one is attentive to the great firing which they hear on all sides; to the manoeuvres of the armies that are engaging; to the decision of an affair of the greatest importance, upon which the fate of each depends. It is then that he can employ his skill to the greatest advantage; strike the severest blow that is possible; cause the ruin of the enemy; pillage the quarters of their generals; carry off their equipages; defeat their guards; set fire to their camp, and spread an alarm over all, which may contribute to the defeat of an army.

But measures must be taken to execute so great, so brilliant a project, with success; and it should not be engaged in, till after having prudently regulated the design on three principal circumstances, viz. the situation of the enemy's camp; the means of approaching it; and the hour of engaging. When the enemy's camp is in the middle of a great plain, or on a height with an extensive view on all sides, it is certain that one cannot approach without being seen at a distance: and in that case, prudence will put a stop to zeal, and prevent rashness from attempting impossibilities; but when their position extends over a country covered with mountains, woods, or villages, the occasion is more favourable, and may almost insure success.

It is then very advantageous for a partisan to be perfectly acquainted with the situation of places that are in front of his army; especially when he foresees that the enemy will sooner or later come to encamp there. What assistance would it not give for the direction of his project, if he knew how to take a plan

of that part of the country which he proposes to invade, before-hand? Then, without the weak and dangerous assistance of spies and deserters, he can by his own proper knowledge think of every means for executing a design, which ought to be regulated and conducted with impenetrable secrecy.

When he perceives by the motions of the armies that they are on the eve of an action, he must not delay to acquaint the general with his project. If he consents, he will regulate the rest, and the time of departure, according to the advices which he receives.

As these sort of expeditions cannot be made but by long circuits, they must take the time necessary for the march. In the campaign of 1757, the duke of Richlieu caused his army to advance near Zell to attack our army; and sent a partisan with 100 horse to the rear of the camp the day before, who, having made a march of 22 leagues, arrived without any accident: but the prudence of the prince of Brunswick defeated his design, and left him to admire his retreat; nevertheless, they picked up some stragglers, horses, and waggons.

Among the measures that ought to be taken to secure the blow, and strike it more effectually, it should not be forgot to distribute cockads like the enemy's to all the cavalry; and to give a tick of six feet long to 20 of each detachment, with a bit of torch fixed on the end, and covered with a little dry straw or hemp, to kindle instantly.

The whole party to set out from the camp A, (fig. 1.) marching under the conduct of a good guide Plate. CCC by covered ways, at a distance from the enemy. Being come to the place C, which ought to be in the environs, and as high as the field of battle, the infantry should be concealed out of the road far from the sight of passengers. This must be the centre of correspondence with the army; the rendezvous of the booty; and support the retreat of all the cavalry, of which there should be as many detachments formed as you purpose to make attacks. We shall suppose six of a hundred men each, and they must go secretly by particular routes to their respective post E, D, F, G, H, I. Neither trouble nor expence should be spared to procure good guides. Each detachment should lie in ambush half a league, if necessary, from the object of the attack, BKKKK.

The noise of the musketry of the armies to be the signal for their irruption; and then bravery, intrepidity, and courage, will give wings to your people. The second detachment D will glance imperceptibly between the villages, and fall like thunder upon the camp B; and while 80 attack all whom they meet, the other 20 should light their torches at the fires that are to be found every where, and spread the flames rapidly to the straw of the tents. As they cannot fail to have the piquet of the camp soon at their heels, they must strike their blow with all possible quickness without stopping to plunder; being content with the glory of having excited a general alarm, capable of confounding the whole army, and contributing to the gaining of a battle.

At the same time that the detachment D attacks the camp B, the others E, F, G, H, must with equal violence attack the villages K, K, K, K, which they have in front, doing the same the first did in camp, except

except that they may plunder every thing which they can easily carry off of the generals equipages, with which these villages are commonly filled; seizing the best horses, hamstringing others with the stroke of a sword, and setting fire to all the places which contain the enemy's baggage. Each detachment should cause some horsemen to advance beyond the village, to observe the motion of the troops that will not fail to run to their assistance. As soon as they perceive them, they must make their retreat as fast as possible by the routes which the commanding officer has premeditated, and which are proposed to be represented by the coarser hatched lines. The sixth detachment I, in ambush on the side of the road leading from the camp, should remain there, to seize all the enemy who think of saving themselves by flight.

There is no danger to be apprehended in these expeditions, during the critical instant while the armies are engaged, and all the troops a great way in the front of the camp; you meet none but sutlers, servants, lame people, and some piquet guards scattered here and there, whom you may easily defeat as they advance. The commanding officer ought to have an eye over all; and as soon as he perceives some bodies of troops advancing upon him, he ought to retreat quickly, and at least gain the entrance of the wood.

Each detachment having rejoined the infantry, must there wait the fate of the battle; so that if it is decided in favour of their army, they may speedily regain the properest places for harassing the enemy on his retreat. These moments are the more favourable, as disorder, dread, and noise, render all defence impracticable. But all these sort of surprises require places proper to cover approaches and retreats.

Having mentioned the necessity of a partisan's being master of the languages, and the advantage deriving from address in carrying a post by surprise, the following instance may serve as an illustration of it.

In the campaign of 1760, that excellent general and true genius of a partisan, the prince of Brunswick, was situated at some distance from Zerenberg, at that time in the possession of the French; and being informed by two Hanoverian officers, who had been in the town disguised like peasants, that the garrison were very remiss in their duty, trusting to the vicinity of their army, and the distance of ours, the prince was resolved to surprise them; and after appointing a corps to sustain him, he advanced in the night with Major Maclean of the 88th regiment; and 200 Highlanders, with bayonets fixed and their arms not loaded, followed at a little distance. Upon the first sentry's challenging, the prince answered in French, and the sentry seeing but two persons advancing, (whom he believed to be French,) he had no distrust; so that the major getting up to him, stabbed him, and prevented his giving the alarm. The Highlanders immediately rushing in, attacked the guard with their bayonets, and carried the town, having killed or taken the whole garrison of 800 men.

The French officer who commanded at that time in Zerenberg concerted a scheme for being amply revenged, which failed only by a most trivial accident. When almost every house in Bremen was filled with corn, being the grand magazine and grand hospital of our army, this officer held a secret correspondence

in the town, which informed him of the state of the garrison, and that there was a general order to let couriers going to the army pass out at all hours. He dispatched about 20 hussars to scamper over the country, who were all that were heard of his party, while he marched 15000 infantry from Duffeldorp to Bremen (about 200 miles), concealing them in woods by day, and marching in the night. He arrived at the gate at the appointed hour; when a person on horseback blowing a horn came along the street, and desired to pass out to the army. The officer of the guard had the keys, and happened to be out of the way; and while a messenger went for him, the people without growing impatient, began to break down the outer barrier, which made the sentry fire at the place where he heard the noise; and the guard taking the alarm, got upon the rampart, and likewise fired at the same place: upon which the pretended courier galloped back; and the French, believing that they were discovered, relinquished their scheme, and retired.

This example proves that no distance is a security from surprises, and that very considerable parties may pass over a great extent of country without being discovered. The following instance of that presence of mind so much the happiness of all who possess it, and more particularly of a military man so exposed to surprises, deserves to be recorded.

In the month of February 1761, when Prince Ferdinand beat up the quarters of the French, they were obliged to retire a great way without being able to resist: However, when they came to collect their force, and to recoil upon our army, Sir William Erskine with the 15th regiment of light dragoons was in a village in our front. In a very foggy morning, soon after the patrols reported that all was well, Sir William was alarmed by his vedettes having seen a great body of cavalry coming to surprise him. He instantly mounted his horse, and sallied out at the head of the piquet of 50 men, leaving orders for the regiment to follow as fast as they could mount, without beating a drum or making any noise. He attacked their advance-guard in the cursory manner of the light cavalry, and continued to do so, while his men were joining him by tens and twenties and the French cavalry forming to resist an attack, till he collected the whole, and then retired, the surgeon of the regiment (Mr Elliot) having in the mean time carried off the baggage.

Strokes of this kind display a superiority of genius, and to that alone was the preservation of the regiment owing. Had a drum beat to arms, the enemy must have known that they were unprepared, and probably would have rushed in and destroyed them; but the attack convinced them that they were discovered, and made them think only of their own preservation.

Among many instances in the course of the war, the success of this officer on another occasion, where he displayed the most singular address, likewise merits our attention. After a repulse, and a march of 72 miles in one day, when the men were fatigued and scarcely a horse able to trot, he saw a regiment of French infantry drawn up with a morass in their rear. He left his own corps, and advancing to the French, desired to speak with the commanding officer, whom he entreated

Fig. 1.

Fig. 2.

to surrender to prevent their being cut to pieces by a large body of cavalry that were advancing. The French officer desired leave to consult with his officers, which having done, they refused to submit; but upon Sir William telling them that their blood must be on their own heads, and turning to move off to his own corps, they called to him, and laying down their arms surrendered to his harassed troops.

Such stratagems overleap the bounds of instruction, and no author will presume to propose them for imitation. Here was the reaching out the hand to fortune which Vegetius recommends: but there are few who have the requisite talents from nature; and we may as properly say of the soldier as of the poet, *nasitur non fit*.

To surprise and carry off some general officer, or other considerable person in some distant place in the rear of the enemy's army, you should take only a detachment of 12 horsemen, known to be worthy the confidence of the commanding officer, and who you can depend upon will not desert to betray you. Each horseman should have a double stoutout with the two sides like two different regiments of the enemy; so that, being perceived under one colour, they may quickly turn them, and appear again under another. This disguise will hinder the country people from making a just report, and agreeing in the route the party have taken. They must take great care to keep at a distance from all roads, and not to stop but under cover. The quarter-master must take care to procure refreshments from some place in the neighbourhood, where they must pay ready money, and not fail to do so till the blow is struck.

SECT. IX. Of Ambuscades from the Partisan.

An ambuscade may be formed in any place covered by art or nature in which a party may be concealed to surprise the enemy in passing; and the proper use of them is, of all the stratagems in war, the best calculated to display the genius, skill, spirit, and address of a partisan. They are easily carried into execution in woods, buildings, and hollow places; but require a more fertile imagination, and greater trouble, in a level country. Both ought to be regulated by the knowledge of the enemy's march, and the extraordinary means that may be employed to surprise them.

When a partisan has information that can be depended on of the march of some part of the enemy; whether a convoy of artillery, baggage, or provisions; a body of recruits, or horses to remount the cavalry; an escort of a general officer going to rejoin, or reconnoitre some country; he ought to apply directly to procure a sufficient knowledge of the route that the enemy is to take, the situation of the places he is to pass, and of the post he goes to. The better to cover his design, he must get information of the roads that lead to opposite places, which he must pretend to be attentive about, as has been mentioned in the section of Reconnoitring.

Having perfectly concerted his plan, he should set out at the head of his detachment if possible, and leaving his post on the side opposite to his true route, the better to conceal his design. If the place where he intends to plant his ambuscade is not distant, he should come into his true route about half way, and there place

half his infantry in ambush to favour his retreat. But when the country where he proposes going is distant, and the march requires at least two nights, he must conduct his party by meandering from wood to wood, if there are any. He must not forget to provide necessary refreshments for the day, which must be passed in some concealed place where he may not be perceived, and must cause three rations of oats to be carried for each horse.

The first night you must make to some wood or other place proper for passing the day near some rivulet, and, if possible, on the road of your retreat to leave a part of your infantry in ambush, in case there is no other water to pass till you come to the place of your principal ambuscade; for when there is still a river or canal to pass you must conduct the infantry to the passage, and choose the most convenient place to fix them in ambuscade.

If there is no bridge or ford, the cavalry must swim over, in which we suppose the horses are practised. When there is a ford, half the infantry should pass behind the cavalry, to go along with them. In case there is a bridge to pass near the village, the officer who is left in this post with some infantry, should be enjoined to allow no one peasant or soldier to leave the place; and for greater security, a small detachment of cavalry should remain with him, to stop any who may attempt to run away before the return of the whole corps, who ought not to delay long. If the enemy come in the interval to attack the bridge, it must be defended till the return of the party, that their retreat may not be cut off.

The following case will prove its importance. The Count Esterhazy being detached with 300 cavalry to levy contributions in the environs of Strasburg, left a lieutenant with 30 men to guard the bridge at Wolfshelm: the lieutenant, from some motive or other, quitted his post, when, happily for the detachment, chance brought Mr Jeney there with 10 chasseurs; and he was scarcely arrived, when he saw three large parties of French hussars advancing to take possession of the passage. He had only time to throw himself with his small party in a hurry into a mill that seemed to command the bridge, and having made loop-holes through the wall, he kept such a constant and deadly fire, that he disputed the passage till Count Esterhazy's detachment, hearing the noise of the musketry, came almost a league, surprised the enemy in the rear, and in five minutes took 80 horses and several prisoners.

Every precaution being taken to guard the bridge, the commanding officer should be diligent to arrive at the place of ambuscade two hours before the enemy is to pass, and place the ambuscade on the side he would retire to; never on the other side, if possible, lest the advanced guard happen to discover you, and oblige you to repass in sight of the corps, who, seeing your strength, may rush upon you and drive you back.

The infantry A (fig. 2.) ought to be ambushed at least 600 paces behind the cavalry B, so that if they are pursued, they can fall back to A, and both afterwards to the guard at the bridge, or to the infantry that are in ambush at half way.

If the ambuscade is placed in a wood, an intelligent non-commissioned officer should be chosen to get upon a high tree C, from whence he can see the march

of the enemy, and give notice of the most essential circumstances. There are three: the first is, the seeing the advanced guard; the second is, the approach of the corps; and the third is, the time when their front is advanced as far as the ambuscade B: for which the commanding officer should instruct the observer what signals he is to make from the top of the tree, to communicate the necessary information without speaking, which may be done by the means of a small cord D, of a brown or green colour, so as to be least perceptible. Let this cord be placed as in the plan, so that no branch interrupt it, with one end in the hand of the observer, and the other in the commanding officer's in the ambuscade B.

As soon as the advanced guard appears, the observer must pull the cord, and the commanding officer cause the party to mount and remain in deep silence. If by a stratagem, which is frequently practised for particular reasons, the advanced guard is immediately followed by the corps, which may easily be known by their being more numerous than ordinary, and not followed by any other corps, that you may not be deceived by the enemy, the cord should be drawn a second time, and a third time when their front is advanced as high as the ambuscade; upon which you must rush out, and pour furiously upon the flank of their centre in the following manner.

If the advanced guard E is formed only of an ordinary number, they should be left pass; and at the approach of the principal party or convoy F, the chief to be informed by the second pulling of the cord. At the moment the head of the convoy shall be advanced as high as B, the cord must be pulled the third and last time; at which signal the whole party must rush out without being perceived, and suddenly attack the centre upon the flank, engaging only with their swords, and making such a noise as to prevent the enemy from hearing the orders of their officers. They must disarm all whom their bravery or chance throws in their way, taking care not to scatter or pursue too far, unless you are sure that they are so far from their army or other parties that they cannot be assisted; for in either of these cases, they will not fail to run at the noise, and disturb your retreat.

In all secret expeditions you ought to be extremely circumspect that you may not be seen or betrayed. If the advanced guard discovers you before the blow is struck, abandon the enterprise immediately, and retire. When your guide, or some one of your party deserts, and you cannot catch them, think immediately of retreating, or placing your ambuscade somewhere else; therefore, to prevent such a misfortune, the officers should be charged to examine frequently if they have all their people.

You should never form an ambuscade for cutting off the enemy's retreat, as this manoeuvre will give him an idea of rallying, and attacking you in despair; but the case is different when you are well informed that you run no risk in stopping his whole force, either from the nature of the defile where they cannot form, or from the smallness of the number which cannot resist.

It is equally difficult and dangerous to form several ambuscades at once; the more are formed, the more they are exposed to be discovered, and less in a state

to unite for a retreat: but we except when they are to be employed to seize foragers; for then it is very proper to form several, and to dispose them in such a manner that the sentries can see from one to another. These dispositions being made, they who chance to be next the foragers must strike the blow, while the others march to secure the retreat of their companions, as soon as they perceive it.

In all ambuscades, no sentries should be placed but officers, or non-commissioned officers. On downs, behind mountains, or in gullies, the sentries should lie with their bellies on the ground, and their feet towards the ambuscade, the body covered with a grey or green cloak, according to the colour of the ground, with their heads a little raised, and wrapped in a handkerchief of a straw-green colour, or white in time of snow, so as not to be perceived. The number of sentries cannot be determined; but should be disposed so as to watch on all sides of the ambuscade, and keep every one who from ignorance approaches too near. The sentries should give notice of what they discover by gestures, to which all the officers should be very attentive.

In countries where there are no woods, vineyards, or hedges, you may place an ambuscade in a field of hemp or corn, or some sort of grain, provided it be high enough to cover you, at least with the help of art. When the stalk of the corn, &c. is not high enough, you must get some of the infantry to work with spades and pick-axes, which they must have brought along with them.

The commanding officer must mark out the ground A (fig. 1.) which they are to prepare for an ambuscade, entering at the side B, and raising in the front and at the two flanks a kind of parapet C, made with an inflexible slope outwards, covered with corn raised from the surface of the ambuscade in form of square turfs of a foot thick D. They should be ranged and placed one against the other till they have gained six feet and a half. If the grain is not more than three feet high, it is plain, that forming the slope imperceptibly to a foot and a half high, with the earth dug of the same depth, the grain which borders the ambuscade will be six feet and a half from the bottom, reckoning the thickness of the turf, which serves to show that such a work ought not to be declined in arable ground so easily worked. When the soldiers have finished the work, a subaltern officer must lead them back to the place destined for the infantry.

The ambuscade being thus made at 100 paces from the road where the enemy are to pass, they should lead the horses into it one after another by the bridle, so as not to enlarge the entry: the horsemen to range themselves standing, and holding the bridles in their hands, with the reins slackened on the horses necks. The officers should be continually employed in visiting the party, and waking those who sleep; and be equally careful to deface all traces of the entry, that none may appear near the ambuscade.

Ambuscades may be placed advantageously in hollow roads when they open obliquely behind that of the enemy, as the road K (fig. 2.) which enters by an acute angle upon the route F of the enemy; nor is there greater difficulty in concealing themselves in the gullies of some rivulet G, when the borders are of a sufficient height, or have shrubs that run parallel

ralled with the road of the enemy. It is extremely dangerous to fix there when the road of the enemy approaches towards, or crosses too near, the ambuscade, as they cannot fail to discover it.

As these gullies are not very large, it is necessary to have a number of ways to rush out quickly on the enemy: We suppose four, H, H, H, H, by which the cavalry can dart out suddenly upon the enemy at F.

It will be proper, before the placing the party, to cause the rivulet to be cut somewhat higher, to give it a new course I, so that the horses feet may be dry in the gullies, and make less noise; and the shorter way they have to go, they will more certainly succeed. The commanding officer will not fail to dispose them in such manner, that the whole can rush out at once by the four passages, and pour in great numbers upon the flank of the enemy.

In such sort of ambuscades, the commanding officer should himself be the sentry, leaning upon the edge, and covering himself so that he may see every thing without being perceived.

In deserted villages they may fix an ambuscade in the gardens G (fig. 1.) or in the barns H. The doors fronting the enemy must be shut up, and the passages which are marked by small dots made use of; for it is a general rule in all ambuscades, to fall forth in such manner as to take the enemy obliquely behind their front.

You ought never to employ infantry in the ambuscades we have been describing, where the cavalry act, unless to favour their retreat: but when you go at hazard, seeking to draw the enemy into an ambuscade, then the infantry should have their turn. Neither woods, villages, nor any places which are much covered, are proper for them; however unskilled an enemy may be, he will not follow a party on the skirts of a forest, or in the neighbourhood of some covered place: for which reason there are no places fitter for succeeding with ambuscades of infantry, than heaths, hilly countries, hollow roads, corn-fields, ditches at the side of great causeways; provided always, that you do not plant them on roads that lead to your army, for then the enemy will take care how he pursues you too far.

When you would place an ambuscade on a heath, or in a country full of little hills, your infantry must lie down with their bellies on the ground. If there is some water near them, it may suggest to them to wet their cloaths and cover them with dust, to give them the colour of the ground: but that this party so laid on the ground may not be crushed or trod upon by the enemy's horse when hurried along with violence, they must preserve the flank of the ambuscade I, next the enemy, with a bar K, which may be made in a hurry with some stakes drove in the ground, at ten feet from one another, and above five or six feet high, held together by cross pieces tied above five feet from the ground, which can be easily done in the neighbourhood of a wood. The time for the infantry to fire, is when the enemy's cavalry L, passing before the front, stretch their flank the whole length of the ambuscade; then your cavalry M, must quickly face about and attack the enemy. Their defeat will be so much the more certain, as the fire of your infantry happens to have driven their squadrons into confusion.

To ambush in the ditch of a great causeway, you

must choose the deepest place, and at the edge of a corn-field which is pretty high, and there place your people sitting or kneeling. You should collect as many small round bushes as possible, which are to be found in plenty in the country, which should be planted, as if naturally, along the side of the road in front of your party, and beyond the ambuscade on the side you expect the enemy, and here and there so open, that the enemy being accustomed to them may pass without distrust. You should then make the corn lean over to cover the ambuscade; but if there is none near enough the ditch, you must have as many squares cut in the manner directed above, as will cover the edge of the ditch. Some of the corn so transplanted should be beat down, but to appear as if done by hail or wind.

Mr Jeney ambushed in this manner with fifty men, when under the command of Captain Palski, who advanced with his cavalry upon the causeway leading to Straßbourg; and as soon as he was perceived, 400 Bavarian dragoons advanced to attack him: he wheeled about, and the dragoons believing themselves masters of the booty, did not fail to pursue, and arrived before the ambuscade without suspecting. Mr Jeney let their front pass, and fired such a deadly fire upon their centre, that he brought to the ground 17 killed or wounded: at the same time, the cavalry who pretended to fly, faced about and attacked the enemy; and would have completed their defeat, if it had not been for the great support of cavalry and infantry hurrying out of Straßbourg to sustain the dragoons; nevertheless he carried off more than 50 horses.

An officer having placed his infantry in ambuscade, ought to send on the cavalry at day-break, a non-commissioned officer with six of the best mounted horsemen making the advanced guard: they should advance as far before the party as the commanding officer can see. At sight of the enemy, they should begin to retire slowly without flying, at least till the enemy comes to pursue with keenness: in that case, the advanced guard makes the rear guard, and may drop a few shot at the enemy, to harass them and draw them on, or make pretended delays to excite them to pursue, till they fall by degrees into the ambuscade.

When you cannot place your infantry in ambush without having a village between them and the enemy, the cavalry should not be sent beyond the village, because the enemy will never expose themselves to cross it in following your party, for fear of falling into some snare: but instead of going beyond it, your cavalry should enter the village, and demand refreshment for 50 men, if the party are 100; then make three or four peasants carry orders to the magistrates of the villages that are towards the enemy, to come to you, and regulate the delivery of waggons and forage, or some other pretence. As the peasants will not fail to acquaint the enemy, and to describe your strength and situation according to what they have heard, the enemy will certainly come with superior force; and that they may come more speedily, they will bring no infantry.

As soon as the peasants are gone, you must be careful to let none of the inhabitants leave the place, and send continually some strong patrols to the rear on the road of your retreat, and especially to the passages by which they can cut off your communication with

the ambuscade. Every horseman holding his horse by the bridle must be ready to mount, so that upon the enemy's appearing, you may retire quickly from the village, and fall back one after another upon your ambuscade.

When a partisan has no infantry, he may form an ambuscade with cavalry, which should be as near as possible to the enemy. In the night, he should send out two or three waggons covered with white linen, that they may be seen at a distance: care must be taken that the harness be in good order, so that no troublesome accident happen by the want of attention to it. Each carriage to have four horses mounted by two dragoons disguised like waggoners, with their arms in the hands of two or four comrades concealed in each wagon, so that they may repulse any patrol they chance to fall in with.

The waggons should go slowly on some road parallel to the front of the enemy, and passing at some distance from their post (for it is not necessary that they pass through them), and regulate their march so, that they may be within half a league of the ambuscade at day-break, and readily perceived by the enemy; then let them stop while one mounts a tree or some height to see round them. When they perceive the patrol of the enemy, they must move off, for the others will not fail to follow; but if the enemy appears not to be inclined to follow, which the non-commissioned officer must attend to, and make one of the drivers stop, as if something were the matter with his wagon, which will draw them on till they fall into the ambuscade.

Among the thousand opportunities that the different marches of the enemy offer for ambuscades, there is none more proper than the retreat of an army which decamps to fall back. When a partisan happens to get information of it on the eve by good spies, he ought to set out immediately with his whole party, making such a round as has been drawn in fig. 1. leaving his infantry in ambuscade at half-way.

The cavalry must be diligent to arrive at the place of ambuscade by day-break, which ought to be placed on the route that the enemy is to take, and two or three leagues in the rear of his camp.

To be more secure of his retreat, he should leave two or three detachments of cavalry between him and his infantry, at a good distance from one another; the remainder to line the road in several ranks parallel to it, and 300 or 400 paces behind one another, concealed from the view of passengers by the favour of hollows, woods, or hills.

The first line being near the road must take care of sutlers, equipages, &c. which are the forerunners of an army, and the first to decamp when they are retreating. When they secure some waggons or mules, the first detachment should pass them to the second, and so on till they come to the infantry.

You must hasten to carry off what you can for a full quarter of an hour; after which you must press your retreat, expecting that the alarm will soon pass to the army, and the light troops be instantly at your heels.

SECT. X. *Of the Retreat.*

EVERY march in withdrawing from the enemy is called a *retreat*. That which is done in sight of the

enemy, who pursues with a superior force, makes the present subject; and is, with reason, looked upon as the glory of the profession. It is a manœuvre the most delicate, and the properest to display the prudence, genius, courage, and address of an officer who commands.

The success of the retreat depends upon the knowledge of the country that is to be passed over, and the goodness of the disposition that is made for the troops to defend themselves. The first offers advantages, and contributes greatly to the seizing them; the second restrains the ardour of the enemy, and keeps up the force of a party to its highest pitch. Both deserve to be studied.

1st, Every officer who commands a detachment ought to apply himself carefully to reconnoitre every step he takes, and examine perfectly every route that can conduct him from one place to another; he should observe attentively all the stratagems that can be employed for ambushing infantry, or posting cavalry; the course of rivers, their bridges and fords; the roads most covered with woods, hills, gullies, and villages; and in a word, he should know all the advantages, as well as the dangers that lie in his way. It will be easy for him to acquire a knowledge of all this, if he will use the method recommended in a former section. With the assistance of such a plan as is there described, he may regulate his retreat with ease, and put it in practice to advantage, profiting by every means proper for his defence, or surprising the enemy.

2^{dly}, The dispositions that ought to be made for a party, to sustain their retreat in the face of the enemy, depend upon the number and kind of troops in both corps; for they must be varied according as they happen to be of cavalry or infantry united, or of either singly.

Every forced retreat in consequence of an unfortunate action, would be almost impracticable, if it were not premeditated before you come in presence of the enemy, or when you are obliged to fly by unknown routes. That which can be made in a fog, or in the night, is easiest, when your rear is secured, as you can slip out of sight of the enemy without any difficulty, and they will be afraid of following you for fear of being surprised in the dark: we shall only therefore speak of that which is to be made in open day, and under the fire of the enemy.

To conduct it properly, you must absolutely know the strength of the enemy; for it is shameful to be the dupe of a false alarm, and to retreat precipitately from an ill-founded fear at the approach of an inferior enemy. You must therefore be convinced of his great superiority, and know what his party consists of.

If they come with a strong cavalry, united to a more numerous infantry than yours, you must immediately render their acting useless, by hurrying your infantry as quick as possible to retreat to the first place where they can lie in ambush, and serve the cavalry advantageously, if they can draw on those of the enemy, as has been said in speaking of ambuscades.

To conceal from the enemy, and favour the departure of your infantry, you should cause your cavalry to advance, and pretend as if they were going to attack the enemy A, (fig. 2.) your party forming into two divisions B and C, each drawn up in two lines, the second double the first, and disposed as in the plan.

The

Fig. 2.

The division C is to retire first 100 or 200 paces, and then fronting the enemy divide into two wings, leaving an interval for the passage of the division B, who, in retiring, must leave a rear-guard at 50 paces, which must be divided into several parties D, to scamper about the enemy's front; and in case they appear desirous to attack you, your small parties must keep a constant fire, particularly on the sides that advance the most; and continue this manoeuvre till they have joined the division C, which should immediately detach some small parties of the best mounted to serve for a rear-guard, and to harraßs the enemy, till the division B is drawn up 100 paces in the rear, and divided into wings, leaving an interval for the division C to pass through in its turn; and continue to manoeuvre it in this manner, till you draw the enemy's cavalry under the fire of your infantry.

When the force of the enemy consists of cavalry alone, your infantry (marked in the plan by dotted right angles) should retire jointly with the cavalry, at least if the country does not expose you to be surrounded by some covered place; because in that case your infantry should go and occupy that place, and form an ambuscade.

The rest of the infantry should place themselves in the second line of each division. If the enemy approaches the first line too near, they should fall lightly back upon the two wings of the second, opening the centre quickly for the infantry to fire upon the enemy in platoons, at the same time that your cavalry detach several small parties to advance briskly to prevent the enemy's forming, who were thrown into confusion by the fire of the infantry. The division which retires will force its march, and go to a greater or less distance according to the pursuit of the enemy. The sustaining division must fall back afterwards till it has passed between the wings of the second division, who must then make the manoeuvre of the first, continuing it alternately till the enemy desists from the pursuit.

To facilitate the retreat of the infantry, and gain some way on the enemy, many have been of opinion that they ought to transport them in waggons. But when the enemy is at our heels, the time is very ill employed in collecting carriages and harnessing them: those moments are too precious; and should be employed in causing the infantry to move off quickly, by which they will not be exposed to a train of waggons taken in haste, which may soon break, or be put out of order, and may stop the whole line; which not only retards the infantry, but likewise the cavalry, when they find the route they were to have taken blocked up with broken carriages.

The case is different when the enemy is at some distance, or that you have already got some way before him; then, if a waggon breaks, it may be thrown immediately out of the road, and each horse of the carriage may carry two soldiers, or be distributed to other carriages. If many are broke, a part of the men should run on foot for some time till they are tired, and then they may change with some of the stoutest, who may afterwards change with others, according to necessity or the possibility of the case.

When there happens to be a wood in your rear, you need not enter it if the enemy follows you close, and is prevented by your strength: it is better to coast

along it by the route marked G, for fear of his coming round you; but if you cannot avoid crossing it, the division C should pass quickly, and at getting out face to the two flanks of the wood. The division B is to remain at the entrance of it, till they judge that the division C is sufficiently advanced, and then fall back, leaving the infantry for a rear-guard during the whole passage through the wood; at which time the whole should resume their first disposition.

In all desiles, and passages of bridges, the same manoeuvre should be used as for woods: but the first division having passed, they should form facing the enemy; and the infantry likewise draw up on the other side, upon the edge of the river.

When the country through which you are to retire happens to be mountainous, the division which falls back should guard the heights by small detached parties, or, if possible, guard them themselves.

A body of cavalry retreating without infantry, ought to form in three lines at 200 paces behind one another; the two last extending their front, that they may appear more numerous, and draw up on the two sides out of the road. The first line being attacked, the second is to sustain it, the third to wait the retreat of the first, and to sustain the second, and continue to do so alternately.

If the enemy seem to quit the pursuit, the whole corps must resume the order of an ordinary march; with this precaution, that the rear-guard be reinforced, and the advanced guard weakened.

As to the retreat of a small detachment of cavalry, such as go to reconnoitre the enemy, to discover their march, to carry off some officer, or for some other commission, as they are not numerous enough to skirmish and retreat by rule, they have but two ways to choose; either to fly, or break through the enemy. They ought to determine for the last, when their retreat is cut off on all sides, so that they have no other way to escape but by cutting their way through the enemy sword in hand: but flight is always less hazardous when it is practicable.

If the officer is certain of the fidelity of his men, and their attachment to him; and sees that they cannot get out of sight of the enemy, but are ready to fall into their hands; he ought to try one means still, which has been known frequently to succeed. He should disperse his party by two and two, by the favour of the first covered place, where they may be at liberty to take so many different routes. It is evident that two men may wind from right to left, and escape more easily than a party of 12 or 20, who cannot move so freely.

Mr Jeney made use of such an expedient successfully in Italy, when the Spaniards having advice of his detachment having slipped to the rear of their army, they cut off his retreat on all sides. The whole party being dispersed, he took two hussars with him, and was followed so close, that every instant he thought he must be taken; however, he saved himself by crossing a marshy pond. The enemy ran to turn him, but he got so far before them, that they could not take him. He got safe to his post, and in three days the whole detachment met without the loss of a man; which will prove, that in such a situation we need not despair, and that in extreme necessity the passage of a river or morass ought not to be declined.

PART IV. OF SIEGES.

SECT. I. Of Attack.

§ 1. *Maxims or principles to be observed in the attack of places.*

1. **T**HE approaches ought to be made, without being seen from the town, either directly, obliquely, or in flank.

2. No more works should be made than are necessary for approaching the place without being seen; that is, the besiegers ought to carry on their approaches the shortest way possible, consistent with being covered against the enemy's fire.

3. All the parts of the trenches should mutually support each other, and those which are farthest advanced ought not to be distant from those which are to defend them, above 120 or 130 fathoms, that is above musket-shot.

4. The parallels or places of arms the most distant from the town, ought to have a greater extent than those which are nearest, that the besiegers may be able to take the enemy in flank, should they resolve to attack the nearest parallels.

5. The trench should be opened or begun as near as possible to the place, without exposing the troops too much, in order to accelerate and diminish the operations of the siege.

There is no such thing as giving any exact rule in regard to the distance which ought to be observed upon opening the trenches. On level ground, this distance may be 800 or 900 fathoms; but if there should be a hollow way in the neighbourhood of the place, the besiegers are to take advantage of it, and open the trenches nearer. In general, they are to regulate themselves upon this head according to the nature of the ground, more or less favourable to the opening of the trenches.—We shall suppose, in the present work, that the opening ought to be made within 800 fathoms of the covert-way; the first parallel within 300 fathoms, the second within 150, and the third at the foot of the glacis.

6. Care should be taken to join the attacks; that is, they ought to have communications, to the end that they may be able to support each other.

7. Never to advance a work, unless it be well supported; and for this reason, in the interval between the second and third place of arms, the besiegers should make, on both sides of the trenches, smaller places of arms, extending 40 or 50 fathoms in length, parallel to the others, and constructed in the same manner, which will serve to lodge the soldiers in, who are to protect the works designed to reach the third place of arms.

8. Observe to place the batteries of cannon in the continuations of the faces of the pieces attacked, in order to silence their fire; and to the end that the approaches being protected, may advance with greater safety and expedition.

9. For this reason the besiegers should always embrace the whole front attacked, in order to have as much space as is requisite to plant the batteries on the produced faces of the works attacked.

10. Do not begin the attack with works that lie close to one another, or with reentrant angles, which would expose the attack to the cross-fire of the enemy.

§ 2. Of investing.

THE first operation of a siege is investing. The body of troops investing a town ought at least to be as strong again as the garrison; they are to divide themselves into several parties, in order to take possession of all the avenues leading to the place. By day they should keep themselves out of the reach of cannon-shot; but as soon as it is dusk they must approach much nearer, the better to be able to support each other, and to strengthen the town.

The investing is generally made by cavalry; but when the country is cut with ravines or hollow ways, or when there are woods in the neighbourhood of the place, then there must be likewise a body of infantry to guard all the avenues, and even to stop up, by a kind of retrenchments, such as might be the easiest to penetrate.

A few days after the investing, the army arrives, and is disposed round the town, according to the ground taken up by the line of circumvallation, and assigned by the engineer who has the direction of the siege. As soon as the place is invested, they begin to trace the line of circumvallation, and afterwards they set about its construction.

§ 3. To trace out the line of circumvallation.

BEFORE a general begins the attack of a place, he must endeavour to have as exact a plan of it as possible, by which he forms a design of the circumvallation and the attacks. The plan is rectified after the investing as much as the vicinity of the enemy will permit; and thereby he may correct the design traced at first, as far as there may be occasion for correction. It is upon such a plan, so rectified, that we suppose a general to proceed. We shall therefore begin with explaining or tracing the operations of the siege on paper; after which we shall give the manner of transferring them to the ground. We shall exhibit the progress of these operations from the investing to the taking of the place, in the order they are really executed. The line of circumvallation being a fortification intended against the enemy from without, who should attempt to succour the town, its defences ought to be directed against that enemy; that is, they ought to be opposite to the town; and the besieging army should, as we have already observed, be encamped behind that line, that is, between it and the town. The camp should be, as much as possible, without the reach of cannon-shot; therefore, as the line of circumvallation should be at a greater distance from the place than the camp, the reason is still stronger for its being also out of the reach of the cannon-shot; which, whether fired horizontally, or at an angle of 10 or 12 degrees, may be reckoned about 1200 fathoms. As the rear of the camp should not be incommoded by the cannon, this part ought to be above 1200 fathoms distant from the place; and we shall suppose that the distance ought to be

be fixed at 1400 fathoms from the covert-way. The depth of the camp may be estimated at about 30 fathoms. From the front of the line of circumvallation there should be a space of 120 fathoms, to draw up the army in battalia behind the circumvallation; which space added to 30 fathoms, supposed for the depth of the camp, gives 150 fathoms; and this, added to the distance from the covert-way to the rear of the camp, gives 1550 fathoms for the distance from the circumvallation to the covert-way.

This being laid down, if the place be a regular octagon, fortified according to M. Vauban's first method *, the radius thereof will be 234 fathoms. This distance being added to the 1550 fathoms, then we shall have 1784. Or we may make it a round number by adding 16 fathoms, which are here of no manner of consequence; and we shall have 1800 fathoms for the distance from the centre of the place to the line of circumvallation.

The radius of the circumvallation being thus settled, from the centre of the place, with the distance of 1800 fathoms, you are to describe the circumference of a circle round the place. The diameter being 3600 fathoms, the circumference will then take 11314; then take the distance of 120 fathoms, which you are to carry to the circumference above described. This distance will be in this example 93 times, and something over, which differs very little from 120 fathoms; so that you may look upon the polygon of this circumvallation as a polygon of 94 sides, of 120 fathoms each.

The polygon of the circumvallation being traced, take on each of the extremities of its sides the lines BD and BE, each of 15 fathoms; and from the points D and E, taken for the centre and distance of 25 fathoms, describe two arcs which cut one another at the point F; from whence draw the lines FD, FE, for the faces of the redans of the line of circumvallation: thus it is we call the salient parts EFD of this line, which serve to flank it.

Perform the same operation on every side of the circumvallation, and then you will have its principal line traced.

The parapet within must be six or eight feet deep; and without make a ditch parallel to all its parts, three or four fathoms in breadth. The parapet of the circumvallation will be seven feet and a half high, and the depth of the ditch equal to the height of the parapet.

We have represented only part of the circumvallation in this figure; we should have had occasion for a very large plate to represent it entire, and in its just proportions.

To make the profile of the circumvallation, let AB be the line level with the country, and CD the scale of the profile. Let A be the side of the town, and B that of the country; take AE, of six feet; from the point E, raise the perpendicular EF, of three feet, and draw the line AF, which will be the talus of the banquette.

Draw FG parallel to AB, three feet from F to G, and the line FG will be the breadth of the banquette. On the point G raise the perpendicular GH, upon the line FG, four feet and a half.

Draw from the point H, HK, parallel to AB.

Make HK seven feet and a half, HI a foot and a half, draw GI, which will be the inside of the parapet of circumvallation.

Draw from the point K, on the line AB, the perpendicular KM; take KL a foot and a half, and draw IL, which will be the upper part of the parapet of the line of circumvallation. Take MN five feet, and from the point N draw the perpendicular NO, and set off seven feet and a half from N to O. Draw OR parallel to AB, three fathoms or 18 feet from O to R; produce the line LN to P, and LP will be the scarp, or the outside of the parapet of the line of circumvallation. From the point R raise RS, perpendicular to OR, or parallel to ON. Make QR equal to OP, and draw QS, which produce beyond S three feet to V; then take SX six feet, and draw VX, and the profile of the circumvallation will be completed.

This kind of glacis, VX, will serve to raise the enemy, and to expose them more to the fire of the line, should they attempt to make themselves masters of it, and to cover the parapet of the circumvallation, in the same manner almost as the glacis of a place covers the top of the rampart.

The dimensions above given may vary a little without inconvenience; but it would be to no manner of use to make the lines stronger; only you may reduce the ditch to ten or twelve feet in breadth at the top, and five or six feet in depth. A ditch of less breadth and depth, besides it is not allowing ground enough to form a good parapet, would have the inconvenience of being too easy to pass over by the enemy.

The lines may be fraised; which is done when they are to last for some time, and the neighbouring country furnishes wood enough for the purpose.

Sometimes a fore-ditch is dug before the lines, 12 or 15 feet in breadth at the top, and six or seven feet deep; it is made about 12 or 15 fathoms from the ditch of the line. The design of it is to stop the enemy when they attempt to attack the lines, and to make them lose both time and men in passing over it. As it is exposed to the fire of the lines, the time the enemy must necessarily spend in crossing will of course occasion their losing a great many men; and besides, the passage itself may throw them into such disorder, as shall prevent their attacking so advantageously as they would otherwise do, were it not for this obstruction.

Notwithstanding these advantages, M. Vauban disapproved of this fore-ditch, from a notion that if the enemy can get there, they are covered against the fire of the circumvallation: and he condemns it expressly in his Memoirs. But, with due deference to this great man, it seems that the engineers have not been all of his opinion upon this matter; and though it be true that the fore-ditch serves as a cover to the enemy when they are in it, yet it retards their march, and keeps them longer exposed to the fire of the lines. Accordingly fore-ditches have been made to lines on different occasions, since the death of marshal Vauban, particularly at Philippsburg. Between this fore-ditch and the ditch of circumvallation, at the siege of Philippsburg, in order to strengthen the defence of the circumvallation, there were likewise dug wells, which were ranged chequerwise, of about nine feet diameter at the mouth, and six or seven feet deep.

They

They were situated near to each other, to prevent the enemy from passing easily through the intervening spaces. The ground they occupied would have been extremely difficult for the enemy to pass; they would have retarded his march; and the fire of the lines, which entirely commanded the passage, would, without doubt, have killed a great many men. The Spaniards practised something of this kind at the siege of Arras in 1654. Before the circumvallation, they dug a number of holes two feet diameter, and a foot and a half deep; in which they fastened stakes that were capable of greatly obstructing the passage of the cavalry. See Plate CCCIII.

A line of circumvallation requires a strong army to defend it. We have found the circumference of the line which we have been now tracing, namely, of 94 sides, each of 120 fathoms, to be 11280 fathoms; out of this number the gorges of the redans are to be deducted, but then their faces are to be added. The gorges have 30 fathoms; and the two faces which have 50, give an overplus of 20 fathoms on each redan; that is, to the number above mentioned of 11280 fathoms, add as many times 20 as there are redans, in order to have the entire circumference of the circumvallation. This circumference has 95 redans; therefore we must add 94 times 20, or 1880, which will make 13160 fathoms for the whole circumference. This number being divided by 2282 (which is the number of fathoms contained in a French league) gives about five leagues and a half. Now it is clear, that so great an extent of ground requires a very numerous army to guard it. We may make a calculation pretty near, by supposing that every soldier drawn up in a line occupies a space of three feet, that is, half a fathom; that the soldiers are four deep; and that the army is drawn up in two lines, which will give eight ranks of soldiers. Each rank containing 26320 soldiers, the circumference of the circumvallation being 13160 fathoms, the eight ranks will therefore make 210560 men.

To these we should likewise add about 12000 or 15000 men for the works of the attack, which would form an army of about 225000 men. And as it is not customary, at least in Europe, to send such strong armies into the field, from whence it follows that the circumvallations, and the lines in general, when they are of a very great extent, are extremely difficult to guard. And indeed the most celebrated generals have been divided in their opinions upon this subject. They all agree that there are certain cases in which they may be of some advantage, especially when they are of a narrower compass, and the design of them is to stop up the entrance of a country of a small extent; but if they are very large, it is extremely difficult to defend them when attacked by a skilful enemy.

It was heretofore the custom to add great outworks to the lines, such as horn and crown works, tenailles, &c. All the circumvallations of the towns that were besieged during the wars between Spain and Holland, under the princes of Orange, were remarkable for this sort of works. These have been since laid aside, because we find that even a line, with its simple redans, is very difficult to guard; and such a number of outworks does but increase its circumference. The modern lines have only a few small half-moons A, before the

gates of the circumvallation, placed like those of the towns, against the middle of the curtains; the entrance is shut up by wooden barriers, and sometimes by chevaux-de-frize, and other contrivances, which will hinder the passage from being easily forced.

The lines having very little elevation, stand in no need of battions to be flanked in all their parts, like those in the circuit of a town. Redans, which are of more simple and expeditious construction, are sufficient. The angle they make with the curtain is always very obtuse, to the end that the soldier being placed on the face of the redan, may be the better able to defend its approach. It is customary, indeed, to make battions in those parts, where the lines form such angles as could not be sufficiently defended by redans. Yet, whenever it may be judged necessary, the line of circumvallation may be fortified with battions. The greatest part of the lines at the siege of Philippsburg was flanked in this manner, as may be seen in Plate CCCIII. The battions increase the circumference of the circumvallation; and probably the reason why they were used at the siege of Philippsburg, was because the circumvallation was of a very small extent.

At the point of the redans, batteries are erected to fire the cannon a barbette over the parapet; and the same is practised wherever the cannon are placed on the line of circumvallation.

A computation is generally made of the time requisite for making the lines, which is very necessary, in order to determine what day the trenches may be opened; this being seldom done till the line of circumvallation is completed. Such a line as that we have been speaking of is, according to marshal Vauban, a work of nine or ten days. When the ditch is narrower, and not so deep, it is made with greater expedition.

The calculation of the time requisite for constructing the lines, is made by measuring the excavation of the ground, of which they are to be formed, by the fathom; or, which amounts to the same, by measuring by the fathom a space of six feet of the length of the line, and computing the time a man will take up in doing it. As the like space is given to each of the workmen, the line is made nearly within the time that one single workman would be about the space assigned him.

Experience shows us, that a workman, in digging of earth of ordinary consistence, may, in a day's labour, dig about the third of a cubic fathom, that is, he may dig such a cube in three days; which will serve to determine pretty nearly the time of the construction of the lines, relatively to their assigned dimensions.

From what we have been saying, it follows, that when we know the circumference of the lines, we know likewise the number of workmen to be employed therein, reckoning one man to each fathom in length.

The workmen employed in the construction of lines are generally peasants, who are ordered for this purpose from the neighbourhood, and who, according to M. Vauban, should have a double allowance of bread given them, that is, one ration more than is allowed to the common soldier. It is not usual to give them any thing else.

When there is no possibility of getting peasants to work on the lines, then the troops are to do it: no part

of Sieges. part of the army is exempt from this duty ; horse and foot must serve alike.

Hitherto we have supposed that the circumvallation was regular ; but even were it irregular, the construction of it would differ very little from that which we have just now given.

A general ought to possess himself of all places from whence the lines may be commanded, when it is possible to do it without carrying the circumvallation to too great a distance ; and that he should take all advantages arising from the nature of the ground, as precipices, eminences, rivers, brooks, morasses, and, generally speaking, whatever is capable of rendering the camp of difficult access. If there are any woods or bushes within its inclosure, it will be right to cover it in those parts by felling the trees, and therewith making a proper fence.

The tracing of the lines admits of no manner of difficulty, if you have a good map of the adjacent country ; since you have only to bring the several parts of the line nearly within 1800 fathoms of the centre of the place, and to take care that there shall be about 120 fathoms from the point of one redan to another.

Nor is there any difficulty in transferring this line to the ground ; the operation is too easy to those who know a little of practical geometry, to lose any time in explaining it here.

§ 4. Of the Park of Artillery.

THE park of artillery is the place which contains the cannon, bombs, powder, and in general all military implements and machines, that have any relation to the artillery.

This park should be placed where there is least danger of being insulted by the enemy, It ought to be without the reach of cannon-shot, and inclosed within a particular spot, which should be fortified also by a line, consisting of a ditch and a parapet, flanked with redans in the same manner as the circumvallation. Nothing should be neglected that is capable of securing it either from the attacks of the enemy, or from any other possible danger.

There are several parks used in a siege ; the great one, which is simply called the park, and is that of which we have been speaking, serves as a general magazine for all the artillery. The little parks are more within reach of the enemy's attacks, and contain the stores and ammunition necessary for daily use ; for which reason they are supplied every day. They are distributed in places where they may be as safe as possible ; and there are as many in number as there are attacks.

§ 5. Of the Line of Countervallation.

THE intent of this line is to secure the besiegers against any attempt from the garrison. It is never made but when the garrison is numerous enough to disturb the besieging army.

It is constructed in the rear of the camp in the same manner, and pursuant to the same rules, as the circumvallation. The whole difference is, that as it is made to oppose a far less considerable body of troops than that which may attack the circumvallation, the parapet need not be so thick, neither need the ditch be so wide nor so deep. The thickness of the parapet may be

only six feet, and the ditch no more than eight feet wide at the top, and five deep. The redans are constructed in the same manner as in the circumvallation ; and a view of the figure * will sufficiently point out whatever relates to this line.

§ 6. Of the Trenches and Parallels.

WHILE the line of circumvallation is finishing, all the materials necessary for the construction of the trenches are got ready, and the engineer, who has the direction of the siege, examines on the spot the most proper place for the attacks, and the figure they ought to have ; and of these he makes a particular plan.

In regard to this subject, there are a great many things to observe. We have supposed that the place is regularly fortified, and on level ground ; so that here it is indifferent on which side the attack is begun. It is sufficient to explain the rules that are to be there observed ; and afterwards to apply them to irregular towns, and to uneven grounds. Let C (fig. 2.) be the place besieged, and A and B the bastions attacked. Begin with indefinitely producing towards the field the capitals of these two bastions ; in like manner produce the capital of the half-moon opposite the curtain between these two bastions ; set off 800 fathoms from the salient angles D and E of the covert-way to F and G. This done, take DH, and EI of 300 fathoms ; and from the centre C, with the radius CH or CI, describe an arc, which produce beyond the points H and I ; and on this arc HI construct the first parallel. Then on the same lines, DF, EG, take the points M and N 140 fathoms distant from the points H and I ; and through these points, describe from the centre C another arc, on which the second parallel is constructed. This second arc will cut the produced capital of the half-moon, in the point L, which is to be observed, in order to begin from hence a trench, which shall extend to the salient angle of the covert-way before this half-moon. Lastly, through the points O and P, the distance of 20 or 25 fathoms from the angles D and E, describe from the centre C, a third arc, on which the third parallel is constructed.

Terminate the first parallel by producing the faces *ab*, *ab* of the half-moons 1 and 2, collateral to the bastions A and B ; but extend the parallel 15 or 20 fathoms beyond the intersection of this prolongation. The second parallel will be less extended than the first, by about 30 fathoms on each side ; and the third also less extended than the second, by about 30 fathoms on each side.

This being done, you have a sketch of the trenches, and the places of arms. The business now is to trace the trenches, or approaches, without being seen or enfiladed.

Take a long ruler, and lay it on the point G, so that it shall make, with the produced capital EG of the bastion B, an angle EGS, whose side GS being produced, shall meet no part of the covert-way, and shall be distant about 10 or 12 fathoms from the angles to which it approaches nearest, and this in order that the trench towards the side GS may not be enfiladed from any part of the covert-way.

Take GS of an arbitrary extent, as of 200 or 220 fathoms, and put the ruler on the point S, so that it

shall make, with GS, an angle GST, the producing of which on the side ST, shall not fall on any part of the covert-way, and it will be 10 or 12 fathoms distant from the most salient parts. Terminate this side in T, and there make also a new angle STI, whose side TI should terminate at the point I, where it meets the first parallel. Perform the like operation on FH, and it will give you the outline of the trenches as far as the first parallel.

At this part of the trenches you may make a greater number of turnings; you may likewise carry it in a direct line to the first parallel. The most important article is, to take care not to let it be enfiladed from any part of the covert-way; and the fewer angles and turnings it makes, the quicker it is constructed, which in transferring it to the ground is worthy of great attention. Mind also, that its extremity, I, does not fall far from the point where the produced capital of the bastion meets the first parallel.

By the same method trace the trenches between the first and second parallel, as may be seen in the figure; but as this part is nearer the place than the former, in order to avoid being raked, it must have a greater number of angles. All its sides ought to cut the prolongment of the capital of the bastion B, as appears by the figure. In like manner trace the trenches between the second and third place of arms, by making as frequent turnings on the produced capital of the bastion B, as shall be necessary, in order to its desiling from the covert-way. By the same method trace the trenches on the capital of the bastion A; trace also a trench on the produced capital of the half-moon, between the second and third parallel, to reach the flank-angle of its covert-way.

When the garrison happens to be strong and enterprising, it will be proper, between the second and third parallel, to make parts of trenches U, U, &c. parallel to the places of arms; they are to be 30 or 40 fathoms long, and to communicate with the trench, as may be seen in the figure. These parts of the parallels are what we have distinguished by the name of *half parallels*, or *places of arms*. Now to trace the whole trenches and the places of arms, of which we have been only giving a sketch or outline, you are, at the distance of 12 feet, to draw parallel to the line we have been tracing, which expresses the trenches, and in like manner to that which expresseth the parallels or places of arms.

At every angle of the trenches observe to produce the part of the trenches in those places, so that this prolongation shall cover that part of the trenches which it terminates.

This will be illustrated by an example.

Let ABCDEFGMQ be a part of the trenches, and let AB be one of the sides opposite to the enemy; produce AB, so that BE shall be five or six fathoms; and in EG, take also five or six fathoms from I to L, which will give the end of the trench BELI, the use of which is to cover the *boyau* or branch IOMG, whereby the enemy will not know the place where it falls into the trench AB, and to make room for withdrawing those who are in this part of the trenches, and that the passage may be free at all the angles. In like manner produce the side GM, from M to N, and the side IC, from O to P, and you will have the end of the trench MNOP, which will cover the branch

DCOQ. Do the same at all the angles of the trench.

The parapet of the trench being made to cover it, the parapet ought to change sides alternately. If, for instance, AE, in the preceding figure, is towards the place, it is evident that the side GN will be towards it also, and likewise the side CD; and therefore the parapet of the trench is successively constructed from the right side to the left, and from the left to the right. In the plans of attacks, the side of the parapet of the trench, as also that of the parallels, are distinguished by a stronger line than any of the rest; but the latter admits of no difficulty, because we may easily conceive, that being parallel to the place, its parapet must necessarily be on the side that faces it. Care has been likewise taken to express, as we have already mentioned, in the figure, the parapet of the branches, by a stronger line than the other lines of the attacks. The side of the trench opposite to the parapet, is called the *reverse of the trench*.

What we have been mentioning is sufficient to trace the trenches upon the plan of a regular place on even ground. In order to give all that can be said relating to this subject on paper, there remains only to add a word or two of their depth, and of their parapet.

The trenches are generally no more than three feet deep; and their parapet, beginning from the bottom of the trench, is six feet and a half high, or thereabouts. The parallels have a parapet like the trench, and of the same height; but as they are intended for firing over, they are made with a kind of banquette, as may be seen Plate CCCV, fig. 3. to raise the soldier, to the end that he may fire over the parapet. On the parapet of the places of arms, are put baskets, fascines, or sandbags, ranged in such a manner that the troops may be able to fire without being too much seen by the enemy. The third parallel, or place of arms, is generally wider than the rest. Sometimes the inside of its parapet is likewise made with steps or banquettes, to the end that the soldiers may conveniently pass over it in case of an attack. The fourth figure of the same plate shews the profile thereof.

There will never be any great difficulty in tracing the attacks, even of an irregular town, and upon uneven ground, from an exact plan, by observing the method we have made use of to make its parts desile properly.

But the difficulty is to transfer the works from the plan to the field, and to direct the attacks of an irregular fortification on irregular ground. By irregular ground we understand that which does not permit an army to extend itself on every side; which is cut by morasses, or subject to be laid under water by the town; or, in a word, which has only some parts fit for continuing the trenches. Here it is that the knowledge of an able and experienced engineer is requisite, in order to obviate the inconveniences of such a spot; a thing that can be done but imperfectly upon paper. Yet to convey some idea of the manner of proceeding, we shall here transfer the above traced attacks to the ground; but to such ground as hath been already mentioned, equally accessible in every part. Before it is done, we must from all the angles of the branches of the trench, upon the plan, draw perpendiculars to the produced capitals; observing the distance of each

Of Sieges. of these perpendiculars and their length. It is evident, that if the capitals were marked on the ground, and it was possible to perform the operations there with any convenience, the trench might be traced with all ease; because by stretching a cord successively from the extremity of one perpendicular to another, you would have the first trace, or the zig-zag, of the trench: but nothing can be traced on the ground; for the operation is to be performed by night, in order to conceal the knowledge of it from the enemy, who will be very little disposed to let the besiegers carry on such an operation unmolested. The following is a method that may be made use of.

The engineer may walk about in the day-time, at a sufficient distance from the place to be without the reach of musket-shot. It is not usual to fire cannon against a single man, because the shot is very uncertain, especially against a person who does not stand still for any time; therefore, without any great danger, he may only keep himself out of musket-shot. It is easy to discover the flanked angle of the bastions against which he wants to direct the attacks, and the salient angle of the covert-way opposite to them: which gives two points, and these the direction or the prolongation of the capitals of those bastions. Consequently he has only to plant some pickets on the direction of these points, in order to have the prolongation of the capitals of the bastions. These pickets can only be put out of the reach of musket-shot; but by day-light he may observe something of the ground lying in the direction of these pickets, and he may afterwards reconnoitre it in the evening, in order to place pickets there also.

In this manner he may have the prolongation of the capitals pretty exact.

In order to conduct the trench by these capitals, the following method has been pointed out by marshal Vauban.

Examine upon the plan of the attacks what distance there is from the beginning of the trench to the first perpendicular; measure this perpendicular and the side or part of the branch corresponding to it; take cords of equal length with these lines, and fasten the extremities of the two cords, one representing the length of the line of direction, and the other that of the branch which makes an angle with it, to a picket at the point of the produced capital where the trench begins, and make two men walk, each of them holding one end of these cords, viz. one in a direct line towards the place, and the other also advancing towards the place and walking along-side of the former. When the first comes to the farthest distance betwixt the opening of the trench and the first perpendicular, he must plant a picket on this point, to which he is to fasten the cord which expresses the perpendicular. He must take the other end of this perpendicular, and afterwards turn off to the right or to the left, according to the side where the perpendicular ought to be, till the part of the cord expressing the perpendicular is well stretched, and joined to that end of the cord of the trench carried by the other man: at their meeting they are to plant a picket, by means of which the triangle, thus transferred to the ground, will be like that which was taken upon the plan; and this part will be traced on the ground in the same manner as on the plan.

1

You may have as many cords as there are windings or turnings in the trench, and you may trace every part of them in the manner above laid down, at least in the beginning, and when the trench is yet at a distance from the place.

Let the trenches be traced upon the plan, (fig. 2.) in the manner already shown, and let C be the place against which you are to direct the attacks, transferring the plan to the ground: let BG be likewise equal to the line of direction of the plan; you are to plant along this line a sufficient number of pickets, with burning matches tied to them, in order to discover them the more easily.

To begin the tracing of the trenches, tie to the picket G a cord of the length GS, and to the same picket another cord of the length GX: let there be two men, and each take an end of these two cords, and let them walk, the one at a venture towards S, and the other directly to X towards the place along the line of direction BG; and having reached the end of his cord, let him fasten it with a picket, after having drawn it very straight; and to this picket let him tie one of the ends of the cord, which is to mark the perpendicular XS. Let him take the other end, and walk towards S till his cord XS is stretched very tight, and then let him join the man who holds the end of the cord GS, and let them fasten a picket in S, where both the cords join. Let them afterwards take away the cord XS, the perpendicular which is of no use, and the cord GS which remains will mark the real tracing of the trenches. In order to have the line ST, you come to the picket X; to which you tie a cord of the length of XY, and another to the picket S of the length of ST. Let two men, as before, take each an end of these two cords, and let them walk, the first who holds the end of the cord XY, directly towards Y, and the other who holds the end of the cord ST, obliquely towards T: he who holds the cord XY, having reached Y at the end of his cord, shall place a picket there; to which let him tie the end of the cord of the perpendicular YT, and let him walk towards T, holding the end of this cord, till he meets or joins the man who holds the end of the cord ST; and at the point T of their meeting, let them place a picket, to which let them tie the end T of the cord ST. After this take away the cord of the perpendicular, and thus continue the same operation as long as you please, or are able, in order to trace all the other turnings or windings of the trenches.

This whole operation supposeth that you know exactly the distance of the point G, the extremity of the line of direction to the top E of the salient angle of the covert-way. To find this distance, many ways may be learnt from trigonometry; but you may make use of the following, which is pointed out by marshal Vauban, and is the most simple.

Let A (fig. 5.) be the vertex of the salient angle of the covert-way, and AB the line of direction of the trench whose length you want to take. At the point B, draw BC perpendicular to AB, to which give what measure you please, as 80 or 100 fathoms, and at the point C, draw CD perpendicular to BC; divide BC into several equal parts, as four, six, or eight, and place pickets in each of these divisions. Walk along CD, and look out for a point on this line,

Of Sieges.

Plate
CCCV.3
Plate
CCCV.

which shall be in the direction of A, and of one of the pickets of BC. Suppose that BC is divided into four parts, and that G, which is the picket of the third division, is in the direction of the point E of the line DC, and at the vertex A of the salient angle of the covert-way, you have the two similar triangles BGA, GCE. Therefore, as BG, the base of the former, is three times GC, the base of the second, it follows that CE is the third of AB, and that thrice CE will give the length AB. If GC was only the fourth part of BG, CE would be only the fourth part of AB, &c.

When once you have found out by this, or such other methods as you may make use of, the length of the line of direction EG, (Plate CCCIV. fig. 2.) you will be always able to know the distance that remains to the salient angle of the covert-way, and to the points I, N, P, through which the parallels or places of arms are to pass. These points being determined, it would be an easy matter from geometry to find out a method of describing the parallels that are to pass through them, if their situation admitted the engineers to perform the operation quietly by day-light; but they are to be traced in the dark, and under the fire of the place; so that there is no other way to trace them than by approximation, that is, to move as nearly parallel to the circuit of the place as you can by your judgment; and to plant pickets, with cords tied to them at proper intervals, the whole length of the line. But you can trace with cords only the first parallel; for the others are too near the place to be able to perform this operation: you are therefore to proceed in tracing them almost in the same manner, as we shall observe when speaking of the sap, to which they belong, and which are carried on by that method.

§ 7. *Observations on the properest part for making the attacks.*

WHILE the lines are perfecting, the necessary materials are to be got ready for the construction and operations of the attacks. The materials consist of fascines, pickets three feet long and about an inch or two in diameter, gabions, and pickets for gabions. There must likewise be a provision of the several instruments or tools necessary for these operations.

The engineer, who has the direction of the siege, will likewise make use of this time to examine into the parts most convenient for carrying on the attacks, and where they will be most simple and expeditious. There are few fortresses in Europe of which plans are not to be had; but as it is presumed that the enemy hath increased the fortifications of a town which is threatened with a siege, care should be taken to get intelligence thereof from some skilful person that has been in the place, and made all the observations possible in regard to the works lately raised, without giving any suspicions of his intentions. The danger of such an undertaking is very well known, so that the person employed cannot be too cautious in keeping himself concealed.

While the circumvallation is making, the engineers may at a distance, or, as we have already observed, out of musket-shot, examine some part of the outworks; and afterwards, from the report of the person sent into the place, and from what they know themselves, they may settle with the general the properest

and fittest place for carrying on the attacks. On this occasion there are many things to be observed, as well with regard to the ground as to the fortifications; but in a work of this nature, it is sufficient to consider the points of most importance.

First of all, the nature of the ground about the place must be well observed, Whether there are any ditches or hollow ways, that may serve as a cover to guards of horse and foot against the cannon of the place; whether there are any parts that command the town, and may serve for the erecting of batteries; and whether the ground is fit for the works. The most favourable circumstance is to find a soil easy to dig; then the works advance with ease and less loss, because the soldier is soon under cover, and the cannon does not do half the mischief as in stony places, where it makes the shivers fly about, which wound a great many men; and besides, instead of sinking as in a good soil, it makes a number of rebounds, which greatly obstruct the progress of the works. If the ground about the place is a pure rock, or a morass, then the operations are still more difficult; besides, there will be occasion for a vast quantity of fascines, sand-bags, wool-packs, &c. and the workmen are in much greater danger.

The rivers which run through the town, or in the neighbourhood, do likewise deserve consideration; for they separate the attacks, and it may happen by some stoppage of the water, or other accident, that the bridges of communication being broke down, the separation of the attacks will expose the army of the besiegers to be defeated, by which means the place may be relieved. It is proper also to inquire, whether those rivers are not subject to inundations, which if they were to happen during the siege, and to break in upon the attacks, would oblige the besiegers to abandon the trenches, and to raise the siege. In a word, whether the town can command any quantity of water so as to make an inundation round the place, and to lay the ground appointed for the attacks under water. All these points, and a great many others which we do not mention, deserve the most serious attention. On the choosing a proper ground for the attacks the success of the siege generally depends; for which reason the engineers and the generals, who are particularly concerned in this choice, spare no pains to obviate every inconvenience that the besieged may make use of to retard the progress of the works. All that the enemy can do ought to be foreseen, in order to prevent or remedy it effectually.

After choosing the properest ground for the attacks, a general is to consider the front which is least fortified and least covered with outworks. All other things being the same, it is evident, that the fewer outworks there are, the easier will be the attack. But if the place is situated in a morass, or upon an eminence, then he is straitened by the ground; for let the outworks of the accessible side of the place be what they will, it must necessarily be attacked on that side. If the town is situated on the bank of a great river, as Mezieres, Namur, Thionville, Strasbourg, Philippsburg, &c. which occupy only one side of it, and maintain the other by little forts; then it is most advantageous to attack that side next the river above or below, flanking the right or left of the trench with the bank of the river, and carrying another trench on

the

the opposite bank, with an intent to take possession of those works, and to occupy a proper situation for placing reverse batteries opposite the grand attacks. In a word, the whole choice of the attacks consists in finding out the properest ground, and the weakest side; but as it is to be presumed that the enemy are acquainted with the nature of the ground about the place, and therefore have taken care to fortify more exactly those parts which are most favourable to an attack, the besiegers should not hesitate to make their approaches on that side; where, by the situation of the ground, they may gain, what the increase of the fortifications might otherwise make them lose.

But in regard to places surrounded with morasses, it is to be observed, that some of those which are looked upon as inaccessible, may happen to be otherwise; and that an exact knowledge of their situation will greatly facilitate the taking of the place, by carrying on the approaches on that side which there is reason to think is less fortified, as the enemy judged it more difficult to attack.

§ 8. *Of opening the trenches.*

EVERY thing being ready for opening the trenches, the ground pitched upon, the attacks settled and drawn upon a plan, and stores or magazines of all the materials necessary on the occasion being within reach of the place where the pioneers propose to work; the general having also settled the round of duty for the guard of the trenches, both of horse and foot, as likewise the number of horse for bringing the fascines, with the number of pioneers and troops to support them; and the chief director of the engineers having acquainted the rest of the corps with his plan of attack, and the manner they are to act; in a word, every thing being ready for execution, the troops designed for the service of the first night being prepared and drawn up in battalia at the place of rendezvous; and the pioneers provided with fascines, pickets, shovels, and pick-axes; in the dusk of the evening they all begin to advance, every soldier being obliged to carry a fascine, together with his arms, in order to reach the place designed for opening the trenches. The guard of horse march at the same time to their assigned posts, to the right and left of the attacks, ready to support the troops for the guard of the trenches in case of any fall from the enemy. All this is to be done with the greatest silence possible, and nothing should be neglected to conceal the design from the enemy.

The pioneers are, according to marshal Vauban, divided into brigades of 50 men each, commanded by a captain, a lieutenant, and two serjants. They advance four or six abreast, near the place where the trenches are to be opened; after which the rest of the troops that are to support them, being come up, the engineers charged with the tracing of the trenches, and who are to place the pioneers, make them come forward where the opening is to commence, while the battalions that support them are drawn up to the right and left in the places assigned them, where they unload their fascines, and silently wait for further orders. In the mean while the engineers trace the branches of the trenches, as we have already observed; the director places the first cord (fig. 2.) from G to S, or

traces the line GS, and the other engineers afterwards trace the other branches from S to T, and from T to I. The same is done on the other side of the attack. The tracing of these two parts is done at the same time; they likewise begin to trace the first parallel this very day, and the work is advanced as fast as possible.

As much work is undertaken as the pioneers can be expected to perform this first night: and in proportion as the tracing goes on, the engineers place the pioneers, making them file off one by one, each carrying his fascine under the right arm if the place is on the right, or under the left if it is on the left, to the end that by the position of their fascines, which they lay on the ground along the tracing, and on the same side as they carry them, they may be enabled to distinguish the side of the place, that is, the side towards which they ought to throw up the ground in order to cover the trench from the fire of the town. As fast as they are placed, they are ordered silence, and made to lie down with their face on the fascines, and not to begin to work till commanded. The whole operation begins at the same time, that they may advance equally. When every thing is ready, and the pioneers are all placed along the tracing which is purposed to be made this first night, orders are again given for them to work; and then they all set about it with all the diligence possible till day-light, that they may be covered against the fire of the place, which is still very dangerous, in the morning, considering that the trench has not had time as yet to be rendered so perfect as it ought. The troops that are to support the pioneers, are put under cover on the back of that part of the trench which is finished; that is, on the border of the trench opposite to that on which its parapet is raised; they are made to lie on their faces; after which the pioneers, who have been upon duty in the night, begin to file off, and others fill up their places.

It is very difficult this first day to render the trench as complete as it should be; but no pains are spared to make it as complete as possible.

As the design cannot be now concealed from the enemy, the guard mounts the next day with drums beating about upon; and care is taken to continue the work of the trenches the second night, in the same manner as the first, that is, by placing the pioneers uncovered, because they are at such a distance from the town, that the fire is not yet dangerous enough to require their being placed otherwise: the work goes on quicker in this manner; but it must necessarily be altered as soon as the workmen come within musket-shot of the place.

If the whole compass of the first parallel has not been undertaken the first night, it is to be done the second; and the branches of the trenches are still carried on, though with less vivacity and progress than the first.

The first night is the best adapted for advancing the works of the trenches, because of the distance from the place, which is too great to apprehend any danger from the enemy's fire. Sometimes it happens so, that the enemy is not apprised of these works; especially when all the necessary precautions have been taken to conceal them, and in that case the business is done in a manner without loss or danger. It is of importance to advance them with quick expedition, that they may be fit to receive the troops, who are to support the pioneers,

in

in order to cover them against the fire of the place: and as the first parallel is designed for this purpose, therefore it cannot be perfected too soon.

This line is made with a view to protect the advanced works, which become more difficult in proportion as they draw near the place; and it is but prudent not to run the risk of their being destroyed by the enemy; for by being too hasty a contrary effect would follow. The grand rule is, not to advance faster than you are able to maintain your ground.

According to marshal Vauban, the first place of arms, though begun the first night, has need of a second and a third, before it can be completely finished and in condition to hold the troops that are to guard the trenches; but the works for perfecting this line will not hinder the besiegers from advancing to the second parallel, which ought not to be begun till the fourth night. It is to be observed, that the guard who mount the trenches are changed every day; they mount about noon, and they are to be as strong as shall be requisite for opposing the sallies which the garrison of the place may make against the workmen. They are generally two-thirds of the garrison, because the enemy may fall upon the trenches with that number, reserving the other third to guard the town. But as it is possible that the besieged may think proper to fall forth with their whole force, and fall upon the workmen, together with the troops that support them; therefore, in order to guard against every accident of that sort, the troops in the trenches ought to be nearly equal to those of the place, especially in small towns, where a few are sufficient to guard the posts, or where the burghers are so well attached to the prince, that the commandant may depend upon their fidelity in guarding the town; because in that case he may make a general effort with his whole garrison against the troops in the trenches.

We have observed, that the second night the pioneers may still be placed uncovered; but the third it would be very dangerous to do it, because of the enemy's fire being too near. When the engineers are of this opinion, they take care not to expose the men any longer uncovered, and then the works are carried on by sap.

§ 9. Of the sap.

Let ABC be the part of the trenches advanced to A, so near the town as to render it impossible, without evident danger, to work any longer at the approaches, unless the men have some cover against the fire of the place: and let the branch AD be traced by the engineer, not with a cord, as at the opening of the trenches, but with some pickets, which he has taken care to place in the direction this branch ought to have, to serve as a guide to the workmen. A cut is made in the parapet BA of the trenches; and then the men designed to work by sap, who are therefore called sappers, will move forward through the opening A, successively eight in number. The first is to roll before him a mantlet, to cover him against musket-shot. He advances as far as is necessary to place a gabion on the line AD; and this gabion being let on its base, in the proper situation, with the pickets uppermost, the sapper makes a little trench behind, about six inches distant from the gabion, of a foot and a half in depth, and as many in breadth, and he empties the earth of

this ditch into the gabion. This done, he places a second gabion near the first, in the same manner, and always under the cover of his mantlet; in like manner he makes a ditch behind, the earth of which serves to fill his gabion. Thus he places a certain number, till he grows tired of the operation.

The second sapper, who immediately follows him, widens the ditch made by the former by six inches, on the opposite side to where the gabions are placed, and makes it half a foot deeper. The earth he digs up serves to fill the gabions of the first sapper. The third sapper widens the ditch of the two first likewise half a foot, and he deepens it in the same proportion.

At length the fourth enlarges it also in the same proportion, in breadth and depth; and then the trench is three feet wide, and the same in depth, which is as much as it ought to be. The earth dug up on this occasion is sufficient, not only to fill the gabions placed by the sappers, but likewise to make a parapet of the rest, which is thrown up, and is strong enough to resist musket-shot. The third and fourth sapper lay the fascines over the gabions, with their hooks, or otherwise; then they press them down, so that the stakes of the gabions shall keep them firm. As the sappers are ranged by brigades of eight each, while the first four are working at the sap, in the manner above described, the other four furnish them with gabions, fascines, and whatever other things they want. But when the first four are tired, the four last take their places, and work in the same manner; after which they are relieved by the first, and so alternately, till each has performed his part at the head of the sap.

When the first gabions are placed, and the sap is not as yet perfected, the part in which the gabions touch one another being less solid than the rest, their joints are filled up by sand-bags, which are taken away when the work is completed, or those interfaces are filled up with small fascines called *sap-sagots*.

This is the nature of the sap; a work so much the more considerable, as it is performed by day as well as night. Several saps are carried on at the same time; and there is one to both sides of each of the attacks for the second and third parallel. There are likewise saps to each of the advanced parts, and to the half-places of arms or parallels.

We have supposed that the first sapper covered himself with a mantlet; this was the custom formerly, and an excellent custom; but now it is more usual to have a stuffed gabion. He rolls this gabion before him, and uses it in the same manner as he would the mantlet. Though care be taken to give a stuffed gabion to the directors of the saps, yet it happens sometimes that the sappers will not make use of them: for as the weight of this gabion renders it sometimes troublesome to roll, they chuse to do without it; and are satisfied with rolling several gabions before them, near one another, and with working behind them. These gabions are indeed of little defence, but are sufficient to conceal them from the enemy, who cannot tell the gabion behind which the first sapper is. But as the preservation of these men is of great importance, they ought to be obliged to work behind the stuffed gabion: for the same reason, the first sappers should have a cuirass, and even a head-piece, musket-proof.

There are three sorts of sap; the limple, viz. that which

Of Sieges. which we have been describing, the double, and the flying sap.

The simple sap, or the sap without any other appellation, is made on one side, or, which is the same thing, has only one parapet.

The double sap has a parapet on each side, and is carried on wherever its two sides are seen from the place.

The flying sap is that in which they do not give themselves the trouble of filling the gabions with earth; it is made where the workmen are not much exposed, and in order to accelerate the approach.

The foregoing account, with the assistance of the figures relative to this subject, is sufficient to give a very exact idea of whatever relates to the sap; we have only to observe, that as soon as the men have brought this work to its proper perfection, the pioneers are ordered forward, and these make it the same width as the other parts of the trenches; upon which it changes its name of sap to that of trench. It is called a trench, if it serves as a way to the town; and a place of arms, if it be parallel to it, and designed to lodge troops.—See Plate CCCV. fig. 7, 8. and CCCVI. fig. 1, 2. See also the upper compartment of Plate CCCII. for figures of the different instruments used in this and other operations of a siege.

§ 10. Of batteries.

CANNON is made use of at a siege for two different purposes; the first to drive away the enemy from their defences, and the second to dismount their guns.

To produce these two effects, the batteries should not be above the mean reach of cannon shot from the place; that is, above 300 fathoms. Therefore there is no possibility of constructing them till the first parallel is formed; and as the distance of this first parallel from the place is generally 300 fathoms, the batteries must be on this line, or beyond it, nearer the town.

In order to judge where they may be placed most conveniently, we are to consider that this must be where they are able to discover or see into a greater part of the enemy's defences. Now this can be no where but on the produced faces of the works attacked. In this situation they discover the whole length of the faces of those works, which they could not do in any other position; therefore we may lay it down as a general rule, always to place the batteries, when the ground will permit, on the produced faces of the works attacked, as we have mentioned in the maxims of attack.

Let Z be the centre of the place attacked, and the trenches, as well as the parallels, completed. To find a proper position for erecting batteries, produce the faces AD, AC, BE, BF of the two bastions attacked, till their prolongation cuts the first parallel. Produce also the two faces OM and OL, of the half-moon MOL of the front attacked, and the faces HG and IK of the two collateral half-moons 1 and 2, to the first parallel, and erect batteries on these produced faces, as you see in P, Q, R, S, T, U, X, and Y.

They are advanced beyond the first parallel 40 or 50 fathoms; and are parted from the trenches, to the end that they may be used with greater ease and convenience, and less trouble to the workmen.

The construction of batteries belongs to the officers of the artillery, who consult with the engineer that

has the direction of the siege, about their situation, and the number of guns.

§ 11. Of sallies.

THAT we might not interrupt the making of the trenches, we conducted them to the foot of the glacis, without taking notice of sallies; that is, attacks which the garrison may make against the trenches, with a view of ruining or retarding the works. As it is not to be presumed that the enemy will suffer themselves to be straitened in the town without using some endeavours to prolong the siege, and as sallies seem to be one of the principal means they can employ, it is proper to point out the conduct to be observed, not only for preventing their effects, but likewise for rendering them disadvantageous to the enemy.

The intent of sallies is to destroy a part of the trenches, to get to some battery in order to nail up the cannon, or to surprise part of the guard in the trenches. When there happens to be a strong garrison, they likewise make sallies without any particular view: but a sensible governor will avoid all such; and we are to suppose that he acts always with one settled design, which is to retard the taking of the place; otherwise he would wantonly expose the garrison, and be the cause of knocking men on the head, without any sort of necessity.

Sallies can be attended with no success, unless they are made at a time when unexpected; by falling then upon the workmen, they are scattered, and obliged to fly. They in running away must needs occasion confusion and disorder among the troops that are to support them; and it requires some time before they can be brought again to order, and made to charge the enemy. In the mean while the latter avail themselves of the opportunity to fill up the trenches, and to do all the mischief possible: but when the troops are upon their guard against every design of the enemy, if the latter stir out of the place, they are suffered to advance; and care is taken to cut off their retreat, by means of the cavalry and the picket, in case they should advance too far into the field: otherwise they are fired at from the places of arms, and other works within reach; and then they are briskly attacked by the grenadiers and the troops upon duty in the trenches. Care, however, must be taken not to pursue them too far, for fear of the fire of the place, which never fails to be extremely sharp when the enemy have got back to the covert-way.

In proportion as the works advance towards the town, sallies become more dangerous to the besiegers, because the enemy may fall upon the trenches more readily; for which reason, double care should be taken to straiten them more closely, and to prevent their falling out with impunity. As the works carried on beyond the second parallel are more exposed than the rest, because of their proximity to the covert-way, no part should be advanced without being well supported. Hence, as we have already taken notice, half-places of arms are formed, in order to support the head of the trenches, till they reach the third place of arms; which must be set about with the greatest care and expedition possible. When this is done in the manner it ought, there will hardly be any farther danger from the sallies.

Sallica

Sallies are seldom made in the day-time but by a presumptuous enemy, who imagine they may safely attack and defy the troops on duty in the trenches: but they are easily repulsed, unless the besiegers are so weak, as not to be able to furnish a sufficient guard for the trenches; in which case they ought not to continue the siege, lest they run a risk of being at length entirely defeated.

A garrison may likewise be in a condition to insult or attack the trenches, after having received a strong reinforcement; and then it is in the option of the general either to continue or to raise the siege. If it appears that his army suffers too much by continuing, he ought to raise it: but here we suppose that he has all the superiority of troops necessary for avoiding such a step, which, independently of the expences incurred in preparing for the siege, and the number of men slain in the different operations, is generally attended with very troublesome and disagreeable consequences.

At the opening of the trenches, and when the besiegers are at a good distance from the place, there is little occasion to be afraid of any sallies in the day; for there would be full time enough to prepare to receive them before they reached the works. If the enemy are disposed then to issue forth, they will do it by night; but it will be an easy matter to get intelligence of any attempt they should make, by ordering parties of 10 or 12 men, headed by a serjeant, to range in the night between the trenches and the town.

These men may lie on their faces as near the place as possible; remaining in profound silence till they hear or perceive some motion in the covert-way; then they should send one of their own body immediately to acquaint the lieutenant-general who that day commands the trenches, and the rest should continue there as long as they can be concealed, to see which way the enemy direct their course. This caution is not only simple and easy, but sufficient to guard the besiegers against surprise, and to enable them to give a warm reception to the enemy.

When the works are advanced pretty near to the place, for instance, to the third parallel, if the enemy should then sally out and fall upon the workmen, the latter must be ordered to retire quickly to the back of the third place of arms, and let the guard fire briskly upon them, without minding the overturning of a dozen or two of gabions; for the galling fire of the small arms, to which the enemy are exposed during this expedition, will make them pay dearly for what little disorder they occasion.

While they are taken up in this business, the besiegers must fall upon them vigorously, and drive them back into the town; taking care, however, not to follow them too far, for fear of being exposed to the whole fire of the place, as soon as the enemy is got back to the covert-way. The mischief they have done is quickly repaired: Marshal Vauban says that one hour is enough for this purpose; and if the fire of the besiegers has been well served, it does more harm to the besieged, than that they can have done to the trenches.

§ 12. *Of the Lodgments on the Glacis, and the taking of the Covert-way.*

We left the works at the foot of the glacis, and at

the third parallel; our business is now to make a lodgment there, and to go on with them till we have driven the enemy from the covert-way.

Our being then so near the covert-way, renders it impossible to desile from it; but in order to prevent the effect of enfilading, it is necessary to make the trenches much deeper in the glacis; the fire of the covert-way being very near, cannot plunge into those deep trenches, which renders it less dangerous to abide there than it would otherwise be were it not for this precaution: or they are made with traverses much in the same manner as in the covert-way, by which means the enfilading will be prevented in part, though not entirely.

And here we are to observe, that the enfilades are far less dangerous when near than at a distance; because it is easier to guard against them by means of traverses. When near, the violence of the fire makes the ball describe a line sensibly direct; so that if it grazes the top of the parapet of one traverse, it will plunge into the next. But in distant enfilades, the balls being at the end of their reach, and having spent their force, they describe lines sensibly different from direct; so that in spite of the traverses and their height, they fall into the part of the trench between the traverses. This is a remark made by Mr Vauban.

In regard to the figure of the lodgment on the glacis, it varies according to the different circumstances or position of the works by which it is defended. The common way is to make several short turnings or zig-zags upon the ridge of the glacis, in the direction of the salient angle of the covert-way, and continued to this angle; or you begin with making two or three short turnings towards the foot of the glacis, from whence you ascend afterwards by a direct trench, or sap, in the following manner.

Two sappers roll each a mantle, or stuffed gabion, before them on the ridge of the glacis; each making a sap, one on one side of the ridge, and the other on the other. The ditch is dug deeper than usual, in order to cover them the better against the fire of the place. This work, which advances on both sides at the same time, and both sides covered, each with a parapet, is what we called a *double sap*. In the middle they make traverses three fathoms thick, and of the same breadth as the trench. On each side small passages are made like those over against the traverse of the covert-way, to the end that the communication thereof be not interrupted.

These traverses are constructed so near to each other, as to be a sufficient cover, by their elevation and distance, against the fire of the place. In order to guard against the effect of the grenades, upon coming within their reach, that is, within 14 or 15 fathoms of the covert-way, care then is taken to cover this trench with blinds, or, which is the same thing, to cover the upper part of it.

The first and second figures of Plate CCCVII. will show this direct trench. The first exhibits the plan, and the second the profile, which passes over one of the traverses.

All this being done, and the third parallel finished in the manner we supposed, they advance from this parallel upon the glacis to each of the salient angles of the covert-way of the front attacked, and they begin with

of Sieges. with making two or three short turnings, as marked on Plate CCCVII. fig. 6. along the ridge of the glacis, so as to occupy about one-third thereof. These are to be made as deep as is necessary, to be a shelter against the fire of the covert-way; afterwards they may proceed directly along the ridge of the glacis, by a deep ditch, to the salient angle of the covert-way. M. Vauban observes, that if we follow directly the ridge of the glacis, this trench is made without much danger. For the palisade which is placed at the salient angle of the covert-way, and the other two next it, do not present directly to the ridge, but only opposite to the faces; where at the most there is only room for one or two fusileers to see the head of the trenches, and who are easily silenced by the fire of the third parallel, which ought to be well served, and likewise by that of the ricochet.

Upon coming to the middle, or two-thirds of the glacis, two new saps are made, *b b*, *ibid.* which embrace both sides of the covert-way, to which they are almost parallel. Their length is 18 or 20 fathoms, and about five in breadth. They are covered at the end with crochets and winding traverses, which prevent the fire of the covert-way from enfilading them easily.

The parapet of these saps is raised about eight or nine feet above the glacis; and by means of gabions, three banquettes are made, as may be seen, Plate CCCVIII. fig. 5. The soldier placed on the upper banquette is thereby raised high enough to plunge into the covert-way, as appears from the same figure. When this work, which Marshal Vauban calls the *cavalier of the trench*, is once finished, it is very difficult for the enemy to remain any where in the covert-way; for they would be too much exposed to the fire of the soldiers placed on these cavaliers. But these places of arms or cavaliers cannot be made without being protected by the ricochet batteries, which enfilade the covert-way.

There is also another method of driving the enemy from the covert-way, which is by using the ricochet bombs. The confusion and mischief they occasion in this part of the fortifications, plainly shows there is no possibility for the enemy to maintain themselves there, so long as this method is practised; as we have observed in the above-mentioned treatise.

These cavaliers being once finished, it is easy to carry on the direct trench, as far as the salient angle of the covert-way, and to establish at the point of this angle and on the head of the glacis a small lodgment bounded by a circular arc; whence the enemy may be entirely driven from the salient place of arms of the covert-way. Afterwards this lodgment may be widened on branches of the covert-way, by digging into the upper part of the glacis, at the distance of three fathoms from the inner side of the covert-way; to the end that this thickness may serve as a parapet to the lodgment, and screen it from the cannon.

The operation we have been describing, to reach from the third parallel to the salient angle of the covert-way, is formed at the same time against all the salient angles of the front attacked: hence the enemy is obliged to abandon them almost all at the same time; and the lodgment on the glacis is afterwards advanced on both sides of these angles, towards the re-entering

places of arms of the covert-way.

As it is impossible to make this lodgment defile from the works of the place, there is no other way to guard against the enemy's fire than by many traverses. The 5th figure of Plate CCCVII. shows in great, the plan of part of this lodgment with its traverses; which are made with chandeliers and gabions. If the enemy, notwithstanding the cannon and bomb-batteries à *ricochet*, and the fire of the cavaliers of the trenches, should obstinately continue in the re-entering places of arms of the covert-way; in order to compel them to remove, batteries for throwing of stones are raised over against those places of arms: and with this view, as soon as the lodgment of the glacis is brought within one-half or two-thirds of the branches of the covert-way, on both sides of the re-entering angle, a sap is carried on opposite to the place of arms; and on this sap batteries for throwing stones are erected, as may be seen in *c c*, Plate CCCVII. fig. 6. These batteries being finished and ready to play, they discharge a shower of stones into the place of arms (fig. 6.), which will not suffer the enemy to maintain themselves there any longer. The lodgment continues to advance; and as soon as the enemy is driven from the place of arms, it is continued all round the faces thereof; and a lodgment is likewise made there, which must communicate with that of its faces, and should extend almost circularly along its demi-gorges. This lodgment being properly finished, will hinder the enemy from venturing to return to the covert-way; and of course will secure the possession of it to the besiegers. These lodgments are made with gabions and fascines; the gabions are filled with earth, fascines are put over them, and the whole is covered with earth; they sink into the glacis as deep as is requisite to be covered against the fire of the place.

In the whole of this account we have not made use of mines; because we were willing that the description of the works, which are carried on from the third parallel, in order to become masters of the covert-way, should be as plain possible. This omission we shall now supply, by making mention of the principal difficulties occasioned by mines, in endeavouring to drive the enemy from the covert-way.

Without mines the enemy would find it very difficult to retard the works we have been describing; because the ricochet batteries must gall them excessively, and break up their defences, so as to deprive them of all shelter: but they may have some resource left in works under ground, where their miners can proceed with more safety; while those of the besiegers, not having the same knowledge of the ground, can only grope in the dark; so that it is altogether a mere chance if they find out the enemy's galleries, and succeed so as to destroy them. If information is received that the glacis is countermined, there can be no manner of doubt but the enemy will avail themselves of their countermines, to carry branches forward into the field; and then to avoid, as much as possible, the mischief that may be done by those subterraneous fires, in the third parallel shafts or pits are sunk eighteen or twenty feet deep, if the ground will permit, in order to get below the galleries of the besieged: and from thence galleries are carried on towards the covert-way, to meet with those of the ene-

my, boring the earth with a long iron needle or augre, to find them out. If they are found underneath, an opening is made down into them, and shells are thrown in, to drive away the enemy and to ruin their gallery. If, on the contrary, they are to be found above them, a small mine must be sprung to break them: but if none of the enemy's galleries can be found, in that case branches must be carried to the right and left; at the end of which are made small chambers, to shake the neighbouring ground, which can hardly misdestroy the galleries and chambers of the besieged.

Notwithstanding all the care that can be taken in the like case, it is not to be presumed that the mines of the besieged under the glacis should be rendered absolutely ineffectual; but as soon as any of them are sprung, workmen are immediately sent to make a lodgment in the pits. In some grounds, the mines of the besieged may be spoiled, by letting in a brook or rivulet into the galleries; for which purpose you have only to dig pits in the neighbourhood, and let the water run in. The expedient was made use of at the siege of Turin in 1706, whereby a great many mines of the besieged were rendered useless.

The enemy should have mines placed, to hinder the lodgment on the head of the glacis, within four or five fathoms of the palisades of the covert-way; to the end that in springing them the palisades may not be hurt, and that they may be under the lodgment which the besiegers make there.

When they have sprung their mines, they make lodgments in them; the besiegers likewise on their part spring mines, with a view to destroy the palisades. In short, nothing is neglected on either side that can help to destroy one another. The besieged do not give up an inch of ground without disputing it manfully; and the besiegers employ every method in their power to oblige the enemy to yield as soon as possible, and with as little loss of men as may be.

Nothing can be said but what is very general on this sort of contests. They depend on the situation of the ground, and upon the capacity and understanding of those who attack, and those who defend the place.

Before we made mention of mines, we supposed, when treating of the lodgment on the top of the glacis, that the fire of the cavaliers of the trenches, together with the cannon and ricochet bomb-batteries, had obliged the enemy to quit the covert-way; but if notwithstanding these fires, they should obstinately continue in the places of arms and behind the traverses, the way to drive them entirely from thence, and to make the lodgment we have been speaking of upon the glacis, is as follows.

Whether the enemy has sprung a mine near the salient angle of the covert-way, or whether the besieged have blown up some of the palisades near it, as soon as the mine is sprung, workmen must be sent to the excavation; where they are to cover themselves with all possible expedition, and afterwards to extend their lodgment in the covert-way on both sides of its salient angle.

The double trench, or the double sap on the ridge of the glacis, must be made to communicate with this lodgment, in order to be able to sustain it if there should be occasion, and to communicate with it more safely. Particular care must be taken to cover the

extremities of it, that is, to make traverses every where, in order to be sheltered from the fire of the other parts of the covert-way, where the enemy still maintains themselves.

When this lodgment is extended to the first traverses of the covert-way, if the enemy keep their ground behind it, as there can be but few under cover there, considering the space they have to occupy, a company of grenadiers must make a brisk attack to drive them away: this done, some of those grenadiers should endeavour to find out in the part abandoned by the enemy the entrance into the mine, and the faucillon; and upon finding it, as there is great probability that they will, they are to cut it off, and thereby render the mine useless. Workmen may be likewise sent into the passage round the traverse, and there make a small lodgment, which will be the safest that can be contrived when the enemy is so very near. After this an entrance is to be dug in the covert-way opposite those traverses, and continued towards the bank of the ditch, under cover of the traverse; then a sap is to be made from each of the extremities of this passage, that is, near the border of the counterescarp; which are to be carried along the rounding of the counterescarp towards the middle, where they are to meet. This lodgment must be made very deep, that it may be no hindrance to that on the head of the glacis; and it is to be managed so as to leave between it and the border of the ditch a breadth of earth, sufficient to resist the cannon of the flanks and the curtain. This lodgment must be also covered with blinds, to prevent the effect of the grenades; and it is of great use towards an opening into the ditch.

During the whole time that the besiegers are working upon this lodgment in the interior part of the covert-way, they are to continue the lodgment on the top of the glacis, as far as the re-entering places of arms; from whence the enemy may be driven by ordering a few companies of grenadiers to attack them, supposing they should be so obstinate as to continue there, notwithstanding the fire of the ricochet batteries, and of the shells and stones. As soon as the enemy have entirely withdrawn themselves, a lodgment must be made there, as we have already mentioned.

§ 13. Attack of the covert-way, sword in hand.

THERE is another method of driving the enemy out of the covert-way, more expeditious indeed, but at the same time more bloody, more precarious, and infinitely less skilful. This consists in making a sudden attack on the whole front of the covert-way, in driving the enemy from thence by main force, and afterwards making good a lodgment.

There may be circumstances that shall absolutely require this method of attacking the covert-way; as when there is no possibility of erecting ricochet batteries to fire at its branches, nor at the faces of the works in the front of the attack; or when it is presumed that the enemy are not in a condition to withstand an attack of this sort; or, in fine, when it is thought expedient to run any hazard in order to be masters of the covert-way a few days sooner: on such occasions it is usual to take this method of attacking it, which is conducted thus.

When the resolution is taken to attack the covert-way

Sieges.
Plate
CCCV.
fig. 4.

way sword in hand*, the third parallel should be made to advance as near as possible to the glacis; and the more forward it is brought, the safer the attack. All along this parallel banquettes are to be made, step-fashion, to the top of its parapet, that the troops designed for the attack may pass over it with ease. At the back of this line, and in the very line itself, a great quantity of materials, as tools, gabions, fascines, sand-bags, &c. must be got ready, that nothing may be wanting to make the lodgment with all expedition, after driving the enemy out of the covert-way. A strong party of grenadiers is ordered, and placed along the third parallel, four or six deep, and the workmen behind them on the back of this parallel with their tools, gabions, fascines, &c. Care, moreover, is taken, that all the other parts of the trenches be well furnished with troops to support the grenadiers, if there should be occasion; and to fire at the enemy's defences wherever they appear: the grenadiers must also be provided with hatchets, to cut down the palisades of the covert-way.

The guns and mortars must be ordered to be ready to support the attack with their whole fire.

A signal is to be agreed on for all the troops that are to commence the attack, to move at the same time, and to fall upon the enemy.

This signal is to consist in firing a certain number of cannon, or a certain number of bombs, and at the last cannon-shot, or at the last bomb, the troops are to move.

The signal being given, all the troops of the third parallel are to move at the same time, and to pass quickly over the parapet of the parallel, and to march directly to the covert-way; which they enter either through the Sally-ports or passages made by the guns, or else the grenadiers cut down the palisades with their hatchets. As soon as they have entered, they charge the enemy vigorously; and when they have obliged them to abandon some of the angles, the engineers set the workmen about making a lodgment on the ridge of the glacis, opposite to that part of the covert-way which the enemy have abandoned, and within three fathoms of the inside of it. This lodgment, as I have observed, is made with gabions, which workmen lay on the glacis on the side of one another. The joints are covered with sand-bags, or with sap-faggots. These gabions are filled with earth and covered with fascines; and a-top of all you are to throw earth taken out of the glacis, by digging and widening the lodgment; and of this a parapet is raised to screen the troops as quick as possible from the direct fire of the place, and traverses are to be made every where to prevent the enfilades, as may be seen in Plate CCCVII. fig. 5. While this is doing, the batteries of the trenches are to fire incessantly upon the defences of the place, in order to disturb the enemy, and to abate as much as possible the briskness of their fire upon the workmen and the lodgment.

When the troops employed in the attack have driven the enemy from the covert-way, or from their places of arms; for it often happens, that at the first attack there can be no more than one or two lodgments made in the salient angles; when this is done, I say, the troops retire behind the lodgment, where they kneel down till it is in a condition to cover them. Some-

times it shall happen that the enemy, who was supposed to have been driven from the covert-way, will return to the charge, and oblige the besiegers to renew the attack, by overthrowing the lodgment and falling upon the troops unawares. This attack may be renewed several times, and vigorously disputed, when there happens to be a strong garrison. In this case the besiegers must exert their bravery, and resolutely encounter every obstacle raised by the enemy.

When the besieged find they cannot hold out any longer, they will let fire to their mines and retire; upon which workmen are sent to make a lodgment in their excavation, as we have already observed when speaking of this attack by the sap. In short, the besiegers are to struggle against every difficulty with all their might; and if they happen to be repulsed at the first attack, they are to begin it again the next day or the day after, and they are to use more precaution than the first time for securing their success.

Before this attack is begun, the besiegers must make a brisk cannonading against the covert-way, in order to break down the palisades, and to demolish the ridge of the glacis, so as to render it easier for the troops to force their way and to make a lodgment upon it. When this is done, the necessary time is to be given for the pieces to cool, that is about an hour, and the attack is to begin in the manner above mentioned; during which the artillery is to play incessantly.

It must be allowed that this manner of attacking is very bloody: for the besiegers must move almost the whole breadth of the glacis uncovered and exposed to the whole fire of the place. They are obliged to attack the enemy concealed behind the palisades, which they are to cut down with hatchets before they can come at them. They are to fight for a long while to an evident disadvantage; and when by dint of valour they have driven away the enemy, they find themselves exposed to the whole fire of the ramparts, which on that occasion is served with more vivacity than usual. They are likewise exposed to the mines which the enemy blow up, with a view to disconcert the lodgment; and to throw the troops into disorder and confusion, which renders it easier for the besieged to return to the charge, and harrahs them anew. But the former method, of which we have above treated, is far from being so precarious and bloody. According to M. Vauban, we ought ever to prefer it when in our power; and to make use of the latter, only when we are obliged to it for essential reasons.

Night is the best time for this attack, because the besiegers are less seen from the place, and of course the fire of the besieged is less dangerous; yet there are generals who undertake it by day. There is nothing settled in regard to this article; they are at liberty to act as they judge most proper, according to the circumstances of time and place.

§ 14. Of the batteries on the covert-way.

When the enemy are entirely driven out of the covert-way, the next thing to be done is erecting batteries, in order to ruin the defences of the place, and to make a breach.

As it is necessary for the besiegers to make themselves masters of the half-moon C (Plate CCCVII.

fig. 6.) before they can come to the body of the place, which is flanked or defended by part of the faces of the bastions A and B opposite to its ditch; they must begin with erecting batteries on the covert-way opposite those parts. They are marked on the plan *e, e*. Batteries must be also erected to make a breach in the half-moon. But before they are erected, it will be proper to consider what part of the face of the half-moon is to be attacked; or, which is the same thing, at what part the half-moon is to be entered. It must not be at its flanked angle, because an opening towards the point would not afford a sufficient space to make a lodgment able to withstand the enemy, and moreover the troops would be seen in their passage by the two faces of the bastions by which its flanked angle is defended. The most favourable passage is towards the third part of its face, reckoning from its flanked angle; because by battering at the same time the two faces near this part, the whole point of the half-moon may be destroyed, and a large opening made there easier than any where else. Thus the batteries for making a breach in the half-moon C, will be placed in *d* and *d'*, and will occupy almost the third part of each of the faces of the half-moon from its flanked angle. These batteries are each to consist of four or five pieces of cannon.

When the faces of the bastions A and B are well enfiladed by the ricochet batteries, there will be no occasion for the batteries *e* and *e'*; for those which are to batter the half-moon in breach will be sufficient; and after it is taken, if there is any necessity for ruining the faces of the bastions A and B, you may make use of the batteries *d* and *d'*, by placing them in *e, e*. Batteries must also be erected to ruin the flanks of the demi-bastions in the front of the attack. It is evident that they cannot be placed but in *i, i*, on the covert-way opposite to them. They ought also to contain as great a number of guns as the space of ground will permit.

For the same reason that batteries have been erected to make a breach in the half-moon, opposite the third part of the face joining to its flanked angle, those also are to be erected which are to make a breach in the bastions; they are marked *k, k*, and are each of seven or eight pieces of cannon. Batteries are likewise erected to ruin the flanks of the demi-bastions bordering upon those of the front attacked, in order to favour the passage over the ditch which is made on the side, upon a supposition that the bastion is entered at both faces, as we suppose in this example. The attacking both faces of the bastion renders the taking of it more certain and easy; but, generally speaking, it is looked upon as sufficient to make only a breach in the face of earth of the demi-bastions towards the front attacked.

Besides all these batteries, others are erected in the re-entering places of arms of the covert-way, as in *l*, and in *k*; they serve to batter the tennaille when there is one, the curtain, and the faces of the bastions, &c. Sometimes they are of mortars for throwing of stones.

All these batteries should have 24 pounders; sometimes larger pieces are used, especially when there is any work of extraordinary strength and solidity to be demolished.

They are all to be placed on the parapet of the

covert-way; and the outside of their epaulement is to graze the inside of the covert-way. It is in order to have room enough for this epaulement, that the lodgment is made on the ridge of the glacis at the distance of three fathoms from the inside of the covert-way.

The only essential thing to be observed in these batteries, is to open their embrasures, so that they shall perfectly discover every part of the place they are to batter, and have a sufficient sloping from the back to the fore-part, to fire as low as the bottom of the revettements, which they are intended to destroy. It is also proper to prevent the enemy's blowing them up with mines: for this end it will be requisite to dig wells deep enough round the batteries, so as to be sure of being lower than the enemy, and to make small galleries round the batteries, in order to discover the branches the enemy have underneath to blow them up.

As the construction of this sort of batteries is very dangerous, being absolutely to be made under the fire of the rampart of the place, they are sometimes masked; that is, before the part where they are erected, sand-bags or some other materials are placed, with a view to shelter the workmen from the enemy.

In order to batter in breach, all the guns should fire together, and towards the same part. They should fire as low as they can, and continue to batter the same part, till the earth of the rampart behind the revettement begins to fall, which is a sign that the revettement is entirely destroyed. This united firing, repeated in this manner against the same place, is productive of a much better effect than if the guns were to be fired one after the other; for not only a greater quantity of the wall is shaken at the same time, but, moreover, the shaking is far more considerable.

§ 15. *Of the descent, and passage over the ditch of the half-moon.*

WHILE the batteries on the covert-way are erecting, preparations are made for the descent and passage over the ditch of the half-moon.

The ditches are either dry, or filled with water, which may be either stagnated, or running; and even into dry ditches the enemy may let in water, only opening the sluices by which it is withheld.

Each of these sorts of ditches requires a different manner of passing. We shall enter here into such particulars as are most necessary for giving a right idea of the method of proceeding.

First of all, if the ditch be dry, and very deep, as from 25 to 30 feet, the descent may be made by one or several subterraneous galleries, passing under the covert-way, and terminating at the bottom of the ditch: the entrance is to begin about the middle of the glacis. These galleries are made like those of miners, and the earth is supported by boards and timber frames. They are directed in such a manner, that the opening in the ditch shall be opposite to that part of the breach where the passage is intended.

As this gallery is made sloping, the business is to have some rule for directing the slope, so as to prevent its being too small or too great: too small, if it terminated above the bottom of the ditch; and too great, if it terminated below it.

The following is a most simple way to find it out.

First

first of all, it is requisite to take the depth of the ditch; which is done by letting fall a plummet, with a string tied to it, from the border of the covert-way to the bottom of the ditch. It is requisite also to know the distance from the entrance of the gallery to the border of the covert-way, which may be easily measured thus: Suppose the depth of the ditch is 30 feet, and that the distance from the entrance of the gallery to the border of the ditch is 90 feet, then by advancing six feet towards the counterescarp, the slope must sink two; that is, there must be always the same proportion between the length of the passage made to approach the counterescarp and the depth of the slope, as between the distance from the entrance of the gallery to the border of the counterescarp and the depth of the ditch: so that if the distance from the entrance of the gallery to the border of the counterescarp is four times as much as the depth of the ditch; then for every four feet advanced horizontally towards the ditch, there must be one sunk perpendicularly, &c. When the ditch is not deep, as of 12 or 15 feet deep, instead of a gallery under ground, the descent is made by a sap only, which cuts the parapet of the covert-way, and sinks therein as deep as is necessary for the descent to terminate at the bottom of the ditch. This sap must begin at the lodgment on the ridge of the glacis; it is secured on both sides with blinds, to support the earth, and it must have a good epaulement on the side exposed to the place. Above it is covered with fascines and with earth, to avoid the shell-stones and grenades that may be thrown in by the enemy. Upon advancing to the foot of the counterescarp, an entrance is made into the ditch.

The enemy will use all their endeavours to hinder this entrance, and to ruin the gallery, chiefly by making small sallies to drive away those who are employed in constructing it: but they must yield at length to numbers. The passage is continued with sapping, to gain the foot of the breach, and by raising an epaulement of fascines, barrels, or old casks, gabions, &c. towards the face of the bastion opposite the passage.

There are generally two or three descents made for the same passage of the ditch, near enough to support each other for greater safety.

It is in the passage of the ditch that the enemy has the advantage in making use of various artifices to retard it. In these they are chiefly assisted by their miners, who blow up the saps by means of small mines, and fall out at the same time, neglecting nothing that can delay the progress of the work. They may likewise order 12 soldiers to fall at once upon the head of the sap: this number is sufficient to drive away the sappers, and to do some damage to that work. A few companies of grenadiers should be placed near at hand, to attack these men as soon as they appear; and the cannon must be kept continually firing against every part, from whence the enemy may possibly fall out. As the batteries of the covert-way command all their communications, they may destroy them, or at least render them very dangerous.

In order to protect the sap at the bottom of the ditch, the besiegers may likewise make use of a kind of small galleries behind the counterescarp, near the place where the entrance is effected; and they may

pierce some loop-holes, from whence the enemy may be fired at, and a check put to their sallies, at least by day: and in regard to night, the besieged ought to be more circumspect than by day, since they can neither see the dispositions, nor the troops that are ordered into the ditch to support the sappers; so that they can only raise a false alarm, without doing any great mischief. Yet we must observe, that this passage can be made only so far as it is protected by the battery placed on the ridge of the parapet of the covert-way opposite the ditch: for as the cannon of this battery keeps continually playing against the defences of this ditch, they must ruin them of course, and destroy their parapet, so that the enemy shall no longer be able to keep any cannon there; the consequence of which will be, that the besiegers have only to force themselves from musket-shot, which is an easy matter.

The passage of the ditch is made on each side of the faces of the half-moon, as may be seen in *m, n, fig. 6. Plate CCCVII.*

If the ditch is full of standing water, and the surface of it be raised to three, four, or five feet, below the upper border of the counterescarp, the descent will be easier; because as the steps are to have but a very small slope, they may begin nearer the border of the ditch, as in the lodgment on the ridge of the glacis, and be directed in such a manner as to terminate at the surface of the water. They are to be covered on the side exposed to the place, and strongly secured with blinds, placed within five or six feet of each other. Blinds are likewise to be laid over the descent, which is to be covered with fascines, and these with earth, to prevent the enemy from setting them on fire.

In order to pass this ditch, a bridge must be made with fascines; for which end, after breaking the counterescarp, a number of men, sufficient to occupy the whole length of the descent, are ranged at the distance of two feet from each other: these men must be covered by the parapet, and are to forward the fascines from hand to hand, from the head of the passage to the opening into the ditch. The sapper in this part (for all these works relate to the sappers) will throw them into the ditch, in order to make an epaulement or covering on that side of the town which looks towards the passage.

As soon as he has flung in a sufficient number of fascines to shelter himself, and to advance a few paces into the ditch, he must throw a great number of them into the passage, in order to fill the ditch up entirely in that part. They are laid different ways, and ranged in different beds, which are covered with earth, in order to make them sink to the bottom. All these different beds of fascines must be fixed with long stakes, that they may keep closer together; and as the work advances, the parapet must be pushed forward, otherwise it would be impossible to effect the passage without the utmost danger.

When the passage is commanded, or fired into from the opposite parapet of the place, or from any other part, the foremost men must be covered with a great heap of fascines, or by some other contrivance; but whatever cover it be, in that case the passage of the ditch is extremely difficult and dangerous.

After what has been said concerning the passage of dry

Of Sieges. dry ditches, and those which are full of standing water, it remains to take notice of those which are full of running water, and those that are dry but may be filled at any time with water. These forts of ditches are extremely difficult to pass, unless the current can be turned and made to take a different course from that which carries it to the town ditches, or unless the besiegers can contrive to break down the sluices which keep up the water referred by the enemy for filling the ditch.

A great deal might be said, were we to enter into the whole detail of the works necessary for passing these forts of ditches; we shall only touch upon the subject.

Supposing the ditches to be filled with running water, or with a river, the channel of which can be diverted no other way, which is called *draining the ditch*, it will be requisite then, generally speaking, to throw into the ditch a large quantity of fascines, loaded with earth and stones, fastened together with long stakes: thus the passage is to be pushed on, till the ditch is contracted to the breadth of 20 or 30 feet; and then small beams may be laid across, to join the bridge of fascines to the rubbish of the breach. The filling up, and consequently the passage of the ditch, may be also forwarded, by ordering the miners to advance to the rubbish, and to spring a mine, in order to blow up part of the revetement of the work into the ditch.

Should the enemy happen to have reservoirs of water which they may open, and thereby destroy the lodgments in the ditch when they are no longer to make a stand there, the besiegers must endeavour during the siege to destroy the sluices, that is, the stone-work or timber that serves to keep up the water. This may be done by throwing a great number of bombs towards that part where the sluices are known to be situated; if they should be broke down by that means, then the water will have a free current; and after it has run off, the passage of the ditch must be attempted in the same manner as if it was standing water; if there remains only a very small current, a passage must be left to drain it, as was mentioned before.

This whole operation is very tedious, difficult, and dangerous; nay, it is impossible to be done at all without being protected by a very brisk firing, not only from all the cannon of the covert-way and the ricochet batteries, but moreover from the lodgments on the glacis and those on the covert-way.

Whatever has been said concerning the passage over the ditch, is general, as well in regard to the ditch before the out-works, as that before the body of the place.

We supposed the ditches had a revetement; but if it was otherwise, the passage would be easier. The descent might be made along the slope of its counter-scarp, and the ditch might be afterwards passed over in the manner already mentioned.

In this whole detail, we have made no mention of cunettes, a kind of small ditch, three or four fathoms in breadth, always filled with water, which is sometimes made in the middle of the great ditch: the reason of our being silent upon this article is, because it can hardly increase the difficulty of passing the ditch.

As soon as the besiegers reach the border of the cunette, they throw in fascines to fill it, as into a ditch full of water; being but narrow, it is the more easily filled up. The difficulty of the passage is increased only when there are caponiers in the ditch to command and enfilade it: then to make the passage of the cunette, the enemy must absolutely be driven from those caponiers. This may be done by showers of shells and stones thrown from the lodgments on the covert-way.

Plates CCCVIII. and CCCIX. will illustrate all that we have been saying upon this head, concerning the descent and passage over the ditch.

Plate CCCVIII. fig. 1. exhibits the plan of the descent under ground, and that of its opening into the dry ditch. Fig. 2. represents the profile of that descent; the opening of which is made at the lower part of the ditch. Fig. 3. is a perspective view of the opening of this descent, seen from the bottom of the glacis: and fig. 4. shows in perspective the opening of the same descent, seen from the top of the breach.

Plate CCCIX. fig. 1. is the plan of the passage over a wet ditch in the open air; that is to say, the gallery of which is an open sap. A is the opening of it. You see in B, towards its opening, the blinds that are laid on its upper part, to support the fascines with which it is covered. On these blinds, at first, is laid a bed of fascines, ranged according to the length of the gallery: over this first bed is laid a second, wherein the fascines are ranged according to the breadth of the gallery, as you see in B and C. D is the epaulement of fascines, which covers the passage against the fire of the place, by which it is flanked. E is part of the bridge of fascines; and F is an elevation also of fascines, intended to cover the head of the work, and to secure it from the immediate fire of the place. Fig. 2. represents the profile of this descent into the ditch. Fig. 3. gives its opening seen in perspective from the country; and fig. 4. its opening into the ditch, also in perspective, as it appears from the top of the breach.

§ 16. *Of the attack of the ravelin, or half-moon.*

THE passage over the ditch before the half moon being effected on both sides, and a breach made 14 or 15 fathoms wide, preparations are made for the assault. For this purpose a large quantity of materials is collected from all the neighbouring lodgments. Endeavours are used to render the breach practicable, by making the slope easy. The cannon continue playing, in order to throw down the parts of the revetement that may be yet standing. Very good use may be also made of shells fired point blank; for they are easily buried in the breach, the earth of which has been already broke up and shaken by the cannon; and as they burst upon that earth, they produce the effect, as it were, of small mines. Howitzers may likewise be used with success on these occasions.

In order to render the breach more practicable, some miners, or a serjeant with a few grenadiers, are sent to level it with hooks. The fire from the lodgments and batteries will hinder the enemy from appearing on their defences; or if they should, they must do it with great circumspection, which renders their fire less dangerous.

If the enemy have made any galleries along the face of the half moon, and opposite the breaches, the miners may go and discover them, in order to stop them up, or to cut off the match, or to drive away the enemy; if they cannot find them, they spring several small mines; which being often repeated, must needs occasion some disorders in the galleries and mines belonging to the besieged. Every thing being ready for making a lodgment in the half-moon, that is, for taking possession of the breach; the materials being at hand, in order to be removed thither with ease and expedition; the batteries and lodgments of the covert-way being in a condition to fire away briskly; a signal is agreed upon with the officers that command those batteries and lodgments, to give them notice to fire, and to leave off whenever it is thought proper. This signal is generally a flag raised in the former case, and lowered in the latter. All this being settled, and the breach, as we observed, made practicable, two or three sappers are sent to the extremity of the breach next to the place, there being generally a kind of small cover or cavity in this part; there they begin a lodgment for themselves, and for some more, who are sent after them; when there is room to receive them, they make them mount, and insensibly extend the lodgment upon the top of the breach; and thus they proceed till they make a lodgment towards the point, which is generally called a *magpye's nest*. While these sappers are at work, the fire of the batteries and the lodgments ceases; but when the enemy attempts to attack the workmen in order to destroy their lodgments, they must retire as quick as possible; and then the colours being raised, the batteries fire upon them with the utmost vivacity, to oblige them to quit the upper part of the breach.

Upon this the colours are lowered, the fire ceases, the sappers return to repair the mischief that was done to their lodgment, and try to enlarge and strengthen it. If the enemy should return, they must retire again in the same manner; and the batteries, as likewise the troops in the lodgments, must renew their fire to drive them from the breach; after which the fire once more ceases, and the sappers return to their work.

This way of proceeding must be continued till the lodgment is in a state of defence; that is, till it can hold a number of troops sufficient to awe the enemy, and to withstand any attack that may happen to be made against it. The besieged, before they entirely quit the half-moon, will spring what mines they have ready there. As soon as this is done, the besiegers should directly lodge themselves in the excavations made by those mines, or at least some defence should be made there, to hold a few sappers, and to forward the lodgments of the inside of the work.

The lodgment of the point is made in the form of a small arc, the concavity of which is turned towards the place. From each of its extremities a lodgment is carried along the faces of the half-moon, on the platform of its rampart, at the foot of its parapet. This lodgment is sunk deep in the earth of the rampart, to the end that the soldiers may be the better covered against the fire of the place; there must be also traverses to secure it from the enfilades, as was done in regard to the lodgment on the glacis. Within side the half-moon lodgments are also made, which

traverse the whole breadth thereof, as may be seen in the half-moon C, Plate CCCVII. fig. 6. They serve to command the communication between the tennaille and the place; of course to render that communication more difficult, and to hold a sufficient number of troops to resist the enemy, should they have any design to return and repossess themselves of the half-moon.

Though the half-moon should happen not to have a revetement, but only to be fraised and palisaded, still the attack ought to be carried on just in the same manner as if there was a revetement; that is to say, the batteries should be disposed in the manner as above laid down; and in regard to the breach, the business then would be only to destroy the fraise, the palisades, and the hedge of the berm (if there should be one opposite the part where the besiegers want to enter the half-moon), and afterwards to take possession of it, and make lodgments, as in half-moons that have revetements.

What we have been observing, in regard to the attack of the half-moon, is only when the besiegers intend to take it by the sap, or with pick-axe and spade: But sometimes they go about it in a more expeditious manner: for when the breach is made so as the troops may mount to enter the half-moon, they advance boldly to the assault, just as in the attack of the covert-way sword in hand, and endeavour to come up with the enemy, and to drive them entirely out of the work. This attack is very dangerous, and may cost a great many men, when there happens to be a brave garrison, who will not easily yield their ground. But there are frequent cases, in which it may be thought prudent to adopt this measure, in order to accelerate a few days the taking the half-moon. As soon as the besiegers are masters of the upper part of the breach, they make a lodgment there in a hurry with gabions and fascines; and while it is making, as also while they charge the enemy, and oblige them to abandon the upper part of the breach, some soldiers are sent to discover the mines, which the besieged are supposed to have made within the inside of the rampart of the half-moon, and to cut off the faucisson. If they cannot find them, they must advance with great circumspection, and take care not to keep all together, that the mine may have less effect. Oftentimes the enemy will suffer the besiegers to carry on their lodgment without making any great opposition, because it cannot be effected without a considerable loss of men, the sappers and the troops being absolutely exposed, during this operation, to the whole fire of the place, which is well served, and by its proximity becomes extremely dangerous: but when the lodgment is advanced, the enemy spring their mines, and return afterwards to the half-moon, in order to retake it amidst the confusion which those subterraneous fires must unavoidably occasion among the troops in the lodgment; in that case, it will be requisite to renew the charge most vigorously with fresh troops, which should be at hand to support those of the half-moon, to place themselves in the excavations made by the mines, to render the lodgment sufficiently strong, and to secure it with a proper number of soldiers, so as to be able to withstand any further attempt of the enemy.

This work can hardly be disputed in this manner, except when the half-moon has a reduit, as it affords

a shelter or retreat to the garrison, and enables them more easily to fall upon the half-moon. For if there should be no reduit, and the enemy are driven out of the half-moon, they can scarce attempt to return, especially if the communication between the place and the half-moon is discovered by the batteries and lodgments of the covert-way: because, if the ditch is filled with water, this communication can hardly be made but with boats, which may be easily seen from the lodgments of the covert way, and may be overset by the cannon of the batteries; and if the ditch be dry, and there happens to be a caponnier, the communication, though more safe, is not without danger, by reason of the fire that may plunge into it from the lodgments of the covert-way; so that it will be extremely difficult for the enemy to advance quick enough to repossess themselves of the half-moon; besides, they want room to assemble in a large body, and fall all at once upon the lodgments of that work.

There is only one case in which they may do it; that is, when in the angle of the gorge of the half-moon they have made a space, nearly as large as the places of arms in the covert-way. This space cannot be seen from the covert-way, nor from its lodgments; and as there are generally steps to ascend from the bottom of the ditch to the half-moon, the enemy might take advantage thereof to try to enter it; but if the besiegers are upon their guard, they will find it easy to repulse them, even with loss; because in that case the enemy have the advantage of situation against them, and are obliged to attack without cover, while the besiegers are sheltered by the lodgment.

The best time for attacking the half-moon sword in hand is by night, for the enemy's fire is not so sure then as by day.

§ 17. *Attack of the reduit.*

WHEN the several lodgments of the half-moon are effected, the enemy will scarce be able to stay any longer in the reduit, especially as the communication between it and the body of the place must become extremely difficult, and is likely to be more so, if the ditch is filled with water, and the bridge of communication between it and the town is demolished by the batteries on the ridge of the glacis: in this case the troops in the reduit will hardly be able to avoid surrendering themselves prisoners of war, as was the case of those who were in the reduit of the half-moon at the siege of Ath in 1697.

To avoid this inconvenience, the enemy generally think proper to abandon the reduit, as it no longer serves to dispute the lodgments of the half-moon, or to afford a retreat to the troops that defend it, when they find themselves incapable of resisting any longer the attacks of the besiegers against this work.

Reduits, generally speaking, consist of a single wall, with loop-holes: but when they happen to have a rampart and a parapet like the half-moon, after taking the latter, the same method almost must be observed in attacking the former; they may be battered in breach, by placing the cannon on the ridge of the glacis of the salient angle of the covert-way, opposite the half-moon to which the reduit belongs. The descent and passage over the ditch is to be made there, just as in the half-moon; and, in short, a lodgment

is effected, either by means of sappers, who are to carry on their work under the protection of the batteries of the covert-way, and its lodgments, or by attacking it sword in hand, as was mentioned in regard to the half-moon.

If the enemy have contrived places of arms at the bottom of the dry ditch of the half-moon *C*, which, as it is well known, do consist only of an elevation of ground that traverses the breadth of the ditch towards the extremity of the faces of the half-moon, in the part opposite to its flanked angle, and which for this reason are sometimes called by no other name than traverses; care must be taken to oblige them to retire from thence, either by the fire of the lodgment on the ridge of the glacis, or by enfilading and firing into them from some lodgments made in the places of arms of the covert-way.

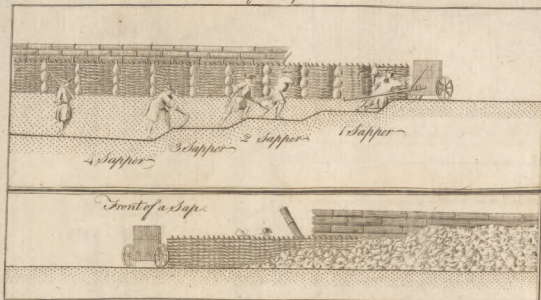

§ 18. *The attack of the bastions.*

WHILE the besiegers endeavour to possess themselves of the half-moon, they work the same time at the descents into the ditch, which are made nearly towards the third part of the faces, reckoning from the flanked angle of the bastion. A descent may be effected at each face of the two bastions in the front of the attack, as in *n, n*, Plate CCCVII. fig. 6. or, according to the more general custom, only opposite the faces in the front attacked. The manner of proceeding is much the same as in the descent and passage over the ditch of the half-moon, whether it be dry or wet; that is, if it be dry, a sap is carried into the ditch, from the opening of the descent to the foot of the breach, and strongly covered towards the opposite flank. If the ditch be full of water, it is passed over on a bridge of fascines, constructed in the same manner as in the passage over the ditch of the half-moon.

The batteries erected on the ridge of the glacis for making a breach in the face of the bastions, must fire against that part of the faces where the breach is to be effected, and fire all together, as was mentioned in the article of the attack of the half-moon: and when they have made a breach sufficient to attempt the attack in front, some of the guns must be kept to batter the upper part of the breach, and some must be removed to the back of the platform, and disposed in such a manner as to be able to annoy the enemy, whenever they present themselves towards the upper part of the breach. All this is done during the descent and passage over the ditch. Mines are also made use of to widen, and sometimes even to make the breach.

To fix the miner to the wall when the ditch is dry, a lodgment is made near the opening of the descent, to protect him from thence against the sallies of the besieged. Then the wall is broke with cannon, as near as possible to the bottom of the ditch, in order to get under the galleries, which the besieged may have built within-side the bastion. An opening of five or six feet may be made with the cannon, to lodge the miner that removes the rubbish, and makes room for one or two of his comrades, who are to assist him to get rid of the earth in the gallery. When the ditch is dry, and the ground will admit of it, the miner sometimes gets under it by a subterraneous gallery, which leads him to the foot of the wall: but if the ditch be filled with water, it is not always the custom

to wait for the completing of the passage over the ditch, before the miner is fixed to the face of the bastion. The wall is pierced with cannon, in the manner before mentioned; but a little above the surface of the water, to the end that the miner may not be incommoded in this gallery; and he is sent over in a little boat, to place himself in the hole. The miners relieve one another every two hours, to carry on their work with more speed; that is, to complete and finish their mine. At the same time the enemy will use various artifices to obstruct them.

When the miner has pierced the wall, he makes behind it, on both sides of him, two small galleries, from 12 to 14 feet, at the end of which he places, on both sides the galleries, two mines, namely, one within the breadth of the wall, and the other sunk 15 feet under the rampart. A common train is given to these four chambers, which taking fire at one and the same time, will produce a very large and spacious breach.

When there are countermine under the rampart, and along its revetment, care must be taken to seize them, and to drive the miners from thence. For this purpose M. Goulon proposes to spring two fougasses near them, in order to burst them; when this is done, he is for entering it with 10 or 12 grenadiers, and as many foldiers, commanded by two sergeants; part of these grenadiers should have each four grenades, and the rest should carry four or five small bombs, of which three only should be charged, the other two with fuses only. The two sergeants should begin with attacking the countermine sword and pistol in hand, and the grenadiers should follow them. If the besieged do not appear to defend their countermine, a lodgment is quickly made with sand-bags. This lodgment consists of no more than a good traverse, which entirely stops up the gallery of the countermine, towards the side from whence the enemy may come. If they attempt to oppose this operation, the grenadiers should throw their three loaded shells, and retire quickly with their comrades, to prevent being hurt by the effect of those shells; for the smoke they make in bursting, together with the splinters, must unavoidably oblige the enemy to quit the gallery for some time: but as soon as they have produced their effect, the sergeant and the grenadiers, with their comrades, must immediately return, and work as hard as possible upon their traverse, in order to stop up the gallery. If the besieged still persist in interrupting this work, the grenadiers must throw the two shells with fuses only, which will oblige the enemy to retire quickly; and as no harm is to be apprehended from them, which is more than the besieged can tell, the besiegers continue to finish the traverse. Even openings or loop-holes are made, in order to fire upon the enemy, in case they should appear again in the part of the gallery opposite the traverse.

When there is no gallery or countermine behind the walls, or when there is one which cannot easily be come at, the miner should leave no means untried to discover it; and at the same time he ought to use the utmost precaution to prevent being surprised himself by the enemy's miners, who will attempt to smother him in the gallery, and to destroy his works: therefore the business of a miner requires great art and cunning to avoid the snare of the enemy. "A miner," says M. de Vauban in his Memoirs, "ought to listen

Vol. X.

"frequently to discover whether there are any at work under him. He ought to found with his augre towards the place he hears the noise come from; but the enemy often make a noise on one side, while they are at work on the other." If their miner draws too near, a small mine must be made to rattle him in the gallery; which may be effected thus: A hole of five or six inches diameter, and six or seven deep, is made on that side the gallery where the enemy is heard; a cartridge of the same size, and containing about 10 or 12 pounds of powder, is put into it: the hole or opening towards the gallery is stopped close with a strong tampon, which is immediately applied to the cartridge, and supported by strong planks well buttressed: this powder is set on fire by a fusee, which passes through a hole made in the tampon, and communicates with the powder in the cartridge. If the gallery of the enemy's miner is within four or five feet of this powder, it will undoubtedly burst, and the miner will be either killed, or obliged by the smoke to retire.

Another way of bursting the gallery of the besieged, when it is at no great distance, is to put several shells on the side where the enemy's miner is at work, and to range them in such a manner that they shall have their effect. When the miners are at work in search of one another, they have great iron borers, with which they pierce the interval betwixt them, to find, as near as they can, their distance from one another. The miner must be very vigilant, and as soon as the borer is withdrawn he should clap a pistol into the hole, which, when well directed, and fired by a man of resolution, seldom fails, as M. Vauban affirms, to kill the miner. The first shot ought to be followed by three or four more; then the hole should be cleaned with the borer, to prevent the enemy from stopping it up on their side: and this is a matter of importance; for it will hinder their miner from continuing his work in that spot, and oblige him entirely to abandon it. These and many other stratagems, which may be seen in the Memoirs of M. Vauban, plainly show that the business of a miner requires not only address and cunning, but likewise great courage and resolution, to guard against and remove the several obstacles that may be thrown in his way, with a view to prevent the progress of the works committed to his direction: he may easily guard against them when he is undermost; but if it be otherwise, his situation is extremely bad. In order to know for certainty whether they are at work under the gallery, the miner generally makes use of a drum with something upon it, and then the flaking of the earth must occasion a kind of trembling, which will discover that they are at work underneath. Sometimes he listens with his ear to the ground; but the fluttering of the drum is the surest way.

While the miner is working upon the construction of his gallery, the besiegers must be employed in demolishing all the works of the enemy, and disabling them from defending or repairing the breach. With this view a continual fire is made against the breaches, which will hinder the besieged from showing themselves in that part, and from advancing to see the works which may be made in the ditch or at the foot of the breaches. If there is a tennelle before the curtain,

batteries are placed in the re-entering places of arms of the covert-way of the half-moon, which plunge into the tenaille, and hinder the enemy from making use of it to disturb the passage over the ditch. And in order to silence them further, another battery of mortars may be erected, in the most advanced lodgment of the gorge of the half-moon; which battery being well served, will render it too dangerous and inconvenient for the besieged to abide there, so as to have the attention requisite for obstructing the passage over the ditch.

But sometimes the enemy will make oblique embrasures in the curtain; and from thence they fire on the lodgments of the covert-way, so as greatly to incommodate both those lodgments, and the opening of the descent into the ditch. The Imperialists, at the last siege of Philipsburg, had made such embrasures in the two curtains of the attack, which would have destroyed a great many men, had the besiegers been obliged to erect batteries on their counter-scarp, and to make the passage over the town ditch. The way to prevent the effect of those batteries, is to endeavour to destroy them with shells; and, when the ground will permit, to enfilade the curtain with ricochet firing. Four or five pieces may be also placed on the upper part of the flanked angle of the half-moon; in which position they can fire directly upon the curtain, and plunge into the tenaille and the postern, by which the enemy keep a communication with the ditch when it is dry. In short, all methods are tried that experience and genius can contrive, to gain a superiority over the enemy's fire, so as entirely to silence it, or at least to hinder them from showing themselves at any of their defences, without being exposed to the fire of the batteries and lodgments.

Let us at present suppose that the passages over the ditches are finished, so as to be fit to walk over; that the cannon or the mines have made the breaches sufficiently wide for the assault; that the ascent is made smooth, and that the besiegers can easily mount to the top of the breach; then they may lodge themselves there, by following either of the two methods mentioned in the article of the half-moon: namely, by sending a few sappers, who, under the protection of the fire of the batteries and the lodgments of the covert-way, shall begin to lodge themselves there; or by ordering a body of troops to take possession of it sword in hand; or, which is the same thing, by attacking the bastion.

If the enemy have made no retranchments in the inside of the bastion, they will hardly venture to stand an assault, as this would only expose the place to be carried sword in hand, themselves to be taken prisoners of war, and the town to be plundered. Therefore every thing being ready for the assault, they will beat the chamade, that is, they will desire to surrender on certain terms.

When a resolution is taken to attack the bastions while the mines are making and charging, a considerable heap of materials is laid up in the lodgments nearest the breaches, that they may be handed readily for the construction of the lodgment, as soon as the enemy is driven away. Every thing being prepared to set fire to the mines, all the grenadiers of the army are ordered to march to the assault; and they are to

be supported by a sufficient number of detachments, that the enemy may not be able to make a stand.

These troops being ready, the mines are sprung; and as soon as the dust is a little laid, the grenadiers, commanded to march and to mount foremost, move on to the foot of the breach; and when they get there, they mount immediately with their bayonets fixed, and are followed by the rest of the troops that are to support them. The enemy will not fail to make use of their mines, if they have any left; and will likewise throw all kinds of combustibles, to make the besiegers pay as dear as possible for the ground which the besieged will be obliged to yield in the upper part of the breach; for yield at length they must, and the superior numbers of the besiegers must surmount every obstacle. If the latter are so fortunate as to repel the first attack, they will not be able to do the same by a second, or a third; in short, they must at length determine to retire behind their retranchments. As soon as they are beaten away, and have abandoned the upper part of the breach, the besiegers must set about making a lodgment; which will consist at first of a kind of arc of a circle, the convexity whereof is turned towards the enemy, if there is a breach in the faces of the two bastions, otherwise it will only be made on the upper part of the breach. The breaches are to be all stormed at the same time; by which means the resistance of the enemy will be divided. This whole time the batteries and lodgments are to fire with all the vivacity possible against the several defences of the enemy, and against every place they are in and that can be fired against, without annoying the troops that are storming the breaches.

The lodgment on the breach being made, the sappers are carried on to the right and left towards the centre of the bastion, and disposed in the manner as in Plate CCCIX. fig. 5. bastion A. Cannon are brought upon the breach to batter the inner retranchment, the ditch is passed over here also, and a lodgment is made upon the breach in the manner mentioned in regard to the bastions.

If behind this first retranchment there was a second, the enemy, after being forced to quit the former, retires to the latter to capitulate. The consequence then would be, to attack them as in the former; and at length they must be forced to surrender. It is very rare to see a defence carried so far as we have here supposed; but it was incumbent upon us to make this supposition, in order to give an idea of what was proper to be done, should the enemy resolve to defend the place to the last extremity.

In attacking the inner retranchments, besides cannon there must be bombs and stone mortars. The bombs do a great deal of mischief, because the enemy are obliged to keep close together in those retranchments, which are always very small; and for this reason the stone mortars are of excellent use, because of the shower of stones which they throw into those works, and which kill and wound a multitude of men.

§ 20. *Attack of a place covered with fore-ditches, lunettes, and other outworks, &c.*

In order to give a more simple idea of the operations of a siege, we have explained and applied them to a place that had no other outworks than half-moons and

Fig. 2.

Opening of the descent into a wet ditch viewed from the Glacis.

Entrance into the descent of the wet ditch viewed from the Breach

Fig. 5.

and a covert way: but a greater number of works will make no alteration in the principles here established: to take, and keep possession of those works, the besiegers have only to follow the same rules; which we shall show in a few words.

Let us suppose a place surrounded by a fore-ditch, and a second covert-way, strengthened with lunettes, and suppose the front by which it may be attacked is covered with a horn or crown work, &c.

First of all the trenches are to be opened as usual, in order to come to the foot of the glacis of the second covert-way; the ricochet batteries are to be placed on the produced faces of the works attacked, and of their defences; the faces of the lunettes of the front attacked ought to be enfiladed by the ricochet batteries.

The second covert-way is taken in the same manner as the common covert-way; and then, if the fore-ditch is full of water, a good lodgment is to be secured along this ditch, and batteries are to be erected to make a breach in the lunettes, if the enemy do not think proper to quit them. It is very difficult for them to maintain themselves in those works, when their communication is seen; and they can hardly avoid being seen, when a lodgment is made all along the fore-ditch. Be that as it may, supposing that they are lined with stone-work, or only with turf, that they are fraied and palisaded, and that the enemy are obstinate in their defence, a breach may be made in them, by placing some cannon opposite the middle of the faces, and the ditch may be passed over by filling it with fascines or some other materials. As it is a great deal smaller than that before the body of the place, it is much easier to pass.

When the besiegers have made themselves masters of the lunettes which cover the front attacked, they begin to think of passing the fore-ditch. This is a very difficult task, because it is performed under the grazing fire of the covert-way; but this fire ought to be checked by the ricochet batteries, which should plunge into the covert-way on every side. This ditch is crossed near the salient angles of the glacis. It is always to be understood, however, that there is no possibility of crossing any ditch without a good epaulement of fascines, to cover the passage on the side which is seen by the place, or by the works that defend it.

When the lodgment is entirely finished on the covert-way, then the other attacks are carried on in the manner before explained.

There are places which, without any fore-ditch, have lunettes opposite to the salient and re-entering angles of the glacis, which are also enveloped by a second covert-way: sometimes they are vaulted and bomb-proof, as at Luxemburg; and sometimes they have only a ditch, a parapet, and a covert-way.

Those which are vaulted and bomb-proof are very difficult to take; because the ricochet-firing and the bombs can do them no mischief. In that case they must either be turned, or be taken by mines.

A work is said to be turned, when the besiegers get between that work and the place, and so cut off their communication. Sometimes the lunettes have communications under ground, and then there is hardly any other way of driving out the enemy but by mines.

This is tedious work; but there is no remedy for it.

The lunettes and the ditch are always defended by branches of the covert-way, with which they have also a communication, like those of the lunettes, A, A, Plate CCCX. fig. 1.

This plate, which represents part of Landau and its attacks in 1713, may serve to give an idea of the manner in which a work is turned. The advanced lunette B, as well as the work C, called a *tenaille*, are turned; that is, the trenches cut off the communication between them and the place.

When this communication cannot be cut off, there will be often a necessity for attacking the lunette and the covert-way at the same time; and the reason is, because though the enemy should be obliged to abandon the lunette, yet so long as they are masters of the covert-way, they have it in their power to return and retake it. Therefore, the sure way of keeping possession of it is to drive the besieged out of the covert-way, at the same time that they are forced to quit the lunette.

The garrison may avail themselves greatly of mines for the defence of these small outworks, so as to oblige the besiegers to pay very dear for their acquisition, and be a long while in making it. But they must pursue the same methods as the besieged; they must dig deep into the earth, they must endeavour to destroy the enemy's mines, to blow up their galleries, and to make themselves masters of the lower ground. This is an essential point, without which the enemy may blow up and destroy the lodgments several times. The celebrated M. de Valiere, in a Dissertation on Mines, at the end of the third volume of M. Folard's Commentary on Polybius, shows that in a ground 25 or 30 feet deep, the enemy may be blown up 20 times. Therefore it is impossible to be too cautious in endeavouring to get under the gallery of the besieged, in order to prevent the mischief they may do by their great number of mines.

In the neighbourhood of some places there are a sort of small half-moons, called *redoubts*. When they are distant from the place, the enemy cannot maintain themselves there without exposing their troops to be taken prisoners of war; but when they are covered and defended as they ought to be, and judiciously situated, they are an object worth attention. Endeavours ought to be used to cut off the communication between them and the place, and to oblige the enemy to abandon them by throwing in shells; it may even be proper to insult them and drive them out sword in hand, provided they are not so near the place as to receive powerful succours and able to withstand the attack. It is a matter of consequence to get rid of these small outworks as soon as possible, because they may be of great hindrance to the progress of the attacks, by having a view of the trenches from the flanks, and enfilading them, &c.

In some sieges, when the garrison are obstinate in their defence, small outworks are made at the foot of the salient and re-entering angles of the glacis; these consist only of a parapet raised at the foot of the glacis upon these angles, each side of which has about 10 or 12 fathoms. These small works are called *arrows*. They may be seen in A, A, A, Plate CCCX. fig. 2. They communicate with the covert-way by a passage pierced on the ridge of the glacis, and palisaded on

both sides. At the entrance of this passage is constructed a traverse B, generally called the *tambour*, which hinders the besiegers from being masters of the arrow, or discovering the inside of the place of arms belonging to the covert-way.

To prevent the effect of these arrows, the best method is to ply them well with ricochet batteries, and with shells thrown in also à *ricochet*. Stone mortars may be likewise made use of, to annoy the enemy in their arrows; for as these works are but small, the stone mortars produce a very good effect. We have already taken notice of almost all the works the besiegers may meet with beyond the covert-way; there remains, therefore, only to see the manner of conducting the attacks of the other outworks most commonly used in fortified towns.

§ 21. Attack of a Horn-work.

A HORN-work is nothing more than the front of a fortification, which projects into the field, and is joined to the place by two long sides. It is placed opposite to the curtains, and sometimes also to the bastions. The besiegers should endeavour, as much as possible, to avoid attacking the side covered by these works, because they are very difficult to take, and of course will greatly lengthen out the siege. But supposing there is an absolute necessity for attacking a place on the side covered by a horn-work opposite the bastion, and that this horn-work has an half-moon opposite to its curtain: The trenches and parallels are to be made in the usual manner; the same method is to be used in regard to the ricochet batteries, which will also enfilade the branches of the horn-work. The taking of the covert-way of the half-moon, and of the half bastions of the horn-work, is carried on in the same manner as the attack of the half-moon, and the two bastions of the body of the place. There remains, therefore, only to show how the lodgments are to be made in this work. We will suppose that there are two retranchments within, as in Plate CCCIX. fig. 5.

When the lodgments towards the point of the half bastions are finished, some guns are to be planted there, in order to batter the face of the opposite bastion; and they are to be placed over against the lodgments of the flanked angles of the half-bastions. These lodgments are to be extended on both sides towards the curtain, along which saps are carried on; as also towards the orillon of the half-bastions, if they are made with orillons: this will form a kind of small parallel, the fire of which will help to cover the lodgments in front, in case the enemy should make any sallies to destroy them. In large fortifications, such as horn and crown works, the lodgments ought to be carried on with the greatest circumspection, in order to be able to support them against every attack of the enemy.

As all these lodgments are commanded by the bastion, it will be requisite to dig the saps sufficiently deep, so as to be secure against their fire; and likewise to make traverses near enough to each other for the same effect.

If the bastion can be battered in breach from the rampart of the half-bastions of the horn-work, the besiegers will for this purpose make use of batteries erected on these half-bastions; and for the same end they

will also plant a battery of six or eight guns towards the middle of the curtain. Should it be impossible to sink sufficiently into these, so as to batter the lower part of the revetment of the bastion, still they might be usefully employed in playing against the enemy's defences, and driving them out of their retranchments. When the lodgments are well secured within, it will be extremely difficult for the enemy to continue in the retranchments, without running the risk of being made prisoners of war; because the communication between them and the place will become too difficult. They might indeed, by means of a bridge level with the water, retire into the collateral half-moons: but at the same time that the besiegers endeavour to make themselves masters of the horn-work, they will also strive to get possession of these half-moons; the taking of which must inevitably follow that of this work.

As soon as the enemy are entirely driven out of the horn-work, the besiegers must possess themselves of it by carrying on lodgments which shall occupy its whole extent; and if there be any occasion to erect batteries within, in order to batter the bastion in breach, they are to be erected along its counterescarp, as may be seen in *z*, (*ibid.*)

Sometimes it shall happen, that the ground of the inside of the horn-work will not permit lodgments to be extended there, as they are ranged in this figure, because it may be too wet and marshy, or else too narrow a circumference. In that case there is no carrying on the lodgments but along the parapet of the front of this work, and along its branches, if the breadth of the platform of the rampart of these branches will permit. It must be made to defile by frequent zig-zags or turnings; but if it be too narrow, the only way for the besiegers is to sink very deep, in order to defile from the fire of the place, and to cover themselves by traverses made very near one another.

Fig. 3.

Of Sieges. made in the horn and crown work of Philipsburg in 1734.

A great deal more might be said, in regard to all these articles; but for the particulars, we refer the reader to the Memoirs of M. de Vauban, which display the whole extent of genius of that great man, and show how capable he was of finding out expedients, for surmounting all obstacles, arising either from soil, situation, or different manners of fortifying.

§ 26. *To prevent succours from being thrown into a town besieged.*

Nor to interrupt the thread of the usual operations of a siege, we have supposed that the general had taken every necessary measure to guard against all the attempts of the enemy, and to secure success by the great superiority of his forces. Sometimes, however, it may happen, that an enemy who was looked upon as too weak to relieve the place, shall prepare to attack the army of the besiegers, either in consequence of drawing out most of the troops from the neighbouring garrisons, which are least exposed, or of having been reinforced from some other part. In such case, there are two ways to follow. The first is, to wait for the enemy in the lines, and to hinder them from breaking through; the second, to leave part of the army in the lines, in order to carry on the siege, and to oppose any sallies of the garrison; with the other to go and meet the enemy, and fight them out of the lines.

Both these ways are supported by the opinion of different generals; but the latter seems to have the most general approbation.

The inconvenience of waiting for the enemy in the lines, is the uncertainty on which side he intends to direct the attack; for which reason the besiegers are obliged to be equally strong in all their posts; and when the line is very extensive, the troops are at too great a distance from one another, to make any considerable resistance on the side where the enemy forms his attack. Most lines of circumvallation, that were ever attacked, have been forced; so that both reason and experience seem to establish it as a maxim, that it is preferable to go and meet the enemy, and not to let him come within reach of the lines.

Without pretending, however, to determine so important a matter, it seems, that when a line is not very extensive, it may be defended to an advantage. And, first of all, it is beyond all doubt, that if the troops behind the line know how to avail themselves of the several circumstances in their favour, their situation is in many respects preferable to that of the assailants. The latter are exposed to the fire of the line for a very considerable time before they can come up to the border of the ditch. This ditch must be filled up; and all the while they are exposed to the same fire, which must kill a great many of their men, and throw their troops into some confusion. And when they break into the line, they can make but a very narrow front; for which reason, they may be charged both in front and flank by the troops within; who, if they do their duty, must drive them into the ditch. For, suppose the first line of the defendants infantry next the ditch should be obliged to give way, the horse that are behind them may and ought to fall upon the enemy's foot that have pierced through the line; and as the

latter cannot force their way but in some confusion, the former may easily drive them out again. Notwithstanding such evident advantages in entrenchments, experience, says the Chevalier Folard, plainly shows, that troops are less brave and resolute behind an entrenchment than in an open field. For they place their whole confidence in this defence; so that when the enemy, to avoid being exposed too long to the fire of the line, jumps boldly into the ditch, and endeavours to mount the entrenchment, the soldier begins to lose his confidence, but loses it entirely as soon as he sees that the enemy breaks through the line. "He looks upon the evil, (says this author), as past relief, when there is nothing easier than to remedy it, by forcing the enemy back again, and tumbling them into the ditch. For, not to mention that they cannot pierce through in good order, they have spent their whole fire. Yet (continues the same author), nothing of all this is done; the enemy enter pell-mell, and form their ranks while the others retire; the terror spreads along the line, they all betake themselves to flight and disperse, without knowing in what manner the enemy forced their way." Upon the whole, we may conclude, that if the troops are sensible of the many advantages of a good line, and are determined to defend it; if the several parts are likewise well supported, and all the necessary precautions have been taken to prevent being surprised; it will be extremely difficult for the enemy to force it.

Thus, at the siege of Philipsburg, in 1734, prince Eugene reconnoitred the lines of circumvallation, and found them so well disposed, that he never once attacked them. They formed a kind of irregular semi-circle round the place, of which the Rhine might be considered as the diameter. They were defended by a kind of fore-ditch, and by wells between this fore-ditch and the lines, as may be seen in Plate CCCIII. If the prince had attempted to pass over this ditch and these wells, they would have lost a great number of men by the fire of the lines. The wells were so near to one another, that there was no possibility of passing between them: they must have been filled up, as well as the fore-ditch, with fascines; which would have been too tedious and dangerous an enterprise.

In such a situation, therefore, the besiegers may wait quietly in their lines; but if they should be of so great an extent, as not to admit of being equally guarded, then it seems to be the safest way to draw out the troops, and meet the enemy, as marshal Tallard did Landau, in 1703. After he had defeated the army which was marching to the relief of the place, he returned and finished the siege. The duke of Vendome acted just in the same manner at the siege of Barcelona, in 1697. Having had intelligence that the marquis of Veleco, viceroy of Catalonia, was preparing to attack him, he went out to meet that general, gained a complete victory, and returned afterwards before the place, which was obliged to capitulate.

At the same time, we must allow that the safest way to conduct a siege, is to have a good army of observation advantageously posted, so that the enemy shall not be able to oblige them to fight, without exposing themselves to a very great risk; and thereby to cover the siege, and be near enough to receive succours

from.

from the troops employed before the town, should the enemy come to a resolution of giving battle.

If the enemy do not think proper to attack the besieging army, they may probably try to throw in some small succours of troops and ammunition into the town. The way to prevent them is to make the circumvallation very exact, and not to leave an opening in it, under any pretext whatsoever.

The enemy may likewise attempt the raising of the siege, by making themselves masters of the spot, or place, from whence the besiegers draw their provisions and ammunition. But before a general lays siege to a town, he should take all the necessary precautions, for securing his magazines, and covering his convoys, and guarding the several posts through which the enemy might march to attack him.

Another expedient the enemy may think of for raising the siege, is to attack some place of importance, which the besiegers have an interest in preserving; in order to engage them to march to its assistance, and to abandon the siege they have in hand. But this expedient ought to have been foreseen, and should not cause the raising of the siege. It is natural for a general, before he thinks of laying siege to a place, to begin with taking all the precautions which prudence and military skill can suggest, for preserving his own country, and covering it against any attack of the enemy. They cannot but think of indemnifying themselves, if possible, for the loss of any place you take from them, by taking some of yours; therefore, as every attempt of theirs must naturally be foreseen, a general should guard against it. However, should the enemy find means to engage in an enterprise of importance, and which requires an immediate relief, if a general thinks there is not time sufficient to take the place he has laid siege to, and at the same time to oppose the enemy's designs, in that case he may raise the siege; but for so doing, there should be very cogent reasons. When king William laid siege to Namur, in 1695, marshal Villeroi, in order to divert him from his purpose, sat down before Brussels, thinking he should oblige that prince to march to its relief, and abandon his enterprise against Namur; but king William chose rather to suffer that city to be bombarded, than to relinquish a very important conquest, in which he was in a manner sure of succeeding.

§ 27. *Of the raising a siege.*

SUPPOSE that, by some one circumstance of those related in the preceding article, or through some other cause, a general finds himself reduced to the necessity of abandoning the siege; in that case, if he apprehends being incommoded by the garrison in his retreat, he ought carefully to conceal his design from them. First of all, the guns and mortars are to be drawn off betimes from their batteries: then the implements are carefully collected, and put into the waggons; and if he intends to steal away unknown to the enemy, all the artillery and baggage must set out at the beginning of the night, the trenches and the places of arms being still filled with troops, who are to continue firing, in order to deceive the enemy; and when the baggage is pretty far removed from the place, all the troops are to follow, while the fires in the camp are left burning as usual. The whole is to

be escorted by horse or foot, according to the country in which the retreat is made, whether through open plains or inclosures. Sometimes it may happen, that a general shall be forced to retire in a hurry, without being able to take all his baggage with him; in such case, whatever he is obliged to leave, must be previously burnt and spoiled, that it may be of no use to the enemy, &c.

When an army is in no danger of being pursued by the garrison in its retreat, the artillery and baggage are sent off by day, and the troops march after them.

SECT. II. *Of Defence.*

§ 1. *Of the troops and ammunition with which a fortified town ought to be provided.*

As the goodness of the works, when a place is well provided with troops, ammunition, and provisions, is what enables it to hold out against the attack of an enemy; so the want of any one of these three articles will not permit all the advantage to be reaped that was proposed in fortifying a town. Men are properly the soul of a defence, and without them the best fortifications in the world are not able to make any great resistance against the enemy.

Therefore we must first of all lay down as a maxim, that a governor cannot make a good defence, unless he hath the number of troops necessary for defending the several posts, and obliging the enemy to pay dear for them. Immense sums are expended in fortifying a place, in order to stop a strong army with a small force; but what resistance can the place make without exerting a brisk fire; and what will those heaps of walls avail, if they are not defended? The garrison of a town besieged ought to have a reasonable stock of provisions, in order to support themselves under the fatigue of military duty; they ought also to have powder, arms, and generally every thing that is requisite to annoy the enemy, and to stop the progress of their operations.

It is not very easy to settle the number of troops necessary to defend a town; the nature of the ground on which the place is situated, and the number of outworks, ought to determine the strength of the garrison. M. Vauban in his Memoirs, reckons, that in a place regularly fortified with good bastions, half-moons, and covert-ways, we should allow 500 or 600 men to each bastion: That if the town has horn-works, 600 men may be likewise assigned to each of those; and in proportion for the other outworks, according to the relation which their defence may require to that of the horn-work. In regard to the horse which they may want on this occasion, he supposes it a tenth part of the infantry.

This being premised, suppose a place has six bastions, there must be a garrison of six times six hundred foot, which makes 3600, and the tenth part of that number in horse, which makes 360. Hence a sufficient garrison for such a place will be 3960 men.

In order to compute, as near as possible, the quantity of ammunition and provisions that may be requisite for such a garrison, we must calculate how many days they will be able to maintain a siege. The following are M. Vauban's remarks on this subject.

| Sieges. | For the investing the place and the tracing the lines | Days. |
|---------|-----------------------------------------------------------------------------------------------------------------------|-------|
| | For the opening of the trenches to the attack of the covert-way | 4 |
| | For the attack and taking of the covert-way, and making lodgments in it | 9 |
| | For the descent and passage over the ditch before the half-moon | 4 |
| | For fixing the miners, or for the batteries till the making of a reasonable breach | 3 |
| | For taking and securing the interior part of the half-moon | 4 |
| | For the passage over the great ditch before the two bastions, supposed to be begun before the taking of the half-moon | 3 |
| | For fixing the miners, or erecting batteries on the covert-way, to lay the place open and make a reasonable breach | 4 |
| | For the defence and support of the breach after the place is laid open | 2 |
| | For the mistakes which the enemy may happen to commit, and their neglect in their works | 4 |

are seldom above two or three attacks at the most, the cannon belonging to those bastions that are not attacked, serve to strengthen the bastions attacked, and they are placed also in the outworks of the fronts attacked.

Among the cannon for the defence of the town there should be some of 24, of 16, of 12, of 8, and of 4 pounders, and even of 2 and 1. The latter are of very great service, because of their being so convenient to remove with ease, and with few men, from one place to another; for this disturbs the enemy, who find it difficult to destroy these small pieces. The largest serve to fire against their batteries and their works. The small ones are carried to the outworks, and to the covert-way, from whence they are fired *in barbette*. It is customary to make use of sea carriages for these small pieces.

Besides cannon, the town ought to be provided with a great number of wall guns, carabines, muskets, &c. We are to suppose that most of the ordinary arms will be broke in the service, and therefore care must be taken to provide new ones when wanted.

The number of mortars necessary may be estimated at two to every bastion. They must be of different bores, of 12 and 8 inches diameter. There ought also to be several stone-mortars.

The garrison of a place of six bastions, consisting, as we have already observed, of 3600 foot, are to be employed or distributed in the following manner.

We should, first of all, reckon about 600 soldiers wounded and sick, in the first 12 or 15 days of the siege, and for the service of the batteries, the removing of ammunition, &c. And then there will remain 3000 for the defence of the place.

These are to be divided into three equal bodies; one for the guard, the other for the bivouac under arms, ready to march on the first notice where wanted, and the third to rest.

The horse are also divided into three bodies like the foot; that for the guard is chiefly placed on the right and left of the attack; that for the bivouac is generally quartered by brigades, in different parts of the town, where they may be of service, either to keep the inhabitants in awe, or to be ready to act in sallies. In regard to the third corps, who are to rest, their horses must be saddled in the day; and the horse or dragoons must be ready to mount instantly, should there be any occasion for their assistance.

The guard of infantry and the bivouac ought to be under arms, at the several posts assigned them in the works of the place; and for the corps at rest, they must be ready to support the troops on guard, in case these should have need of their assistance.

The guard of foot of 1000 men, may be subdivided nearly into three equal bodies; two of which to defend the posts attacked, and the third the other posts not attacked. And in regard to the two first, they may be subdivided also into three equal bodies; two of which are to fire the first two hours of the night, the other is to relieve one of them at the end of that time, the next is relieved two hours after; and so on alternately, that there may be always two-thirds of this guard in action, and the other third at rest.

There is no occasion for so brisk a firing by day as by night; because the besieged are more capable of

Total of the defence 41
In this defence it is plain we suppose a town to be fortified only with half-moons and a covert-way; but if the half-moon had a reduit with a revettement and rampart, it might hold out four days longer.

If there were retrenchments in the bastions, they might retard the taking of the place five or six days.

If the ditch was strengthened with tenailles and caponiers, the passage over it might be protracted two or three days.

If there was a good horn-work, or some other like fortification properly strengthened with a half-moon, a covert-way, and retrenchments within the work, the taking of it would cost about 12 or 14 days.

If this work had tenailles, the passage over its ditch would be later by two or three days.

If there was a fore-ditch and a second covert-way, the progress of the attacks would still be less rapid, and we might reckon 10 or 12 days for the taking of this second covert-way and the passage over its ditch.

If there were redoubts near the place, they would still protract the taking of it for some days.

From this estimate, though not very exact, an idea may be formed of the duration of a siege: a point absolutely necessary for securing, at least, a sufficient quantity of ammunition during the time; we say at least, because it is always prudent, if possible, to have a greater quantity of ammunition than is supposed to be wanted.

When once the number of the garrison, together with the duration of the siege, is fixed, it is then very easy to calculate the quantity of powder and ammunition with which the place is to be provided. We shall give here an estimate, after mentioning a word or two in regard to the necessary quantity of cannon, mortars, &c. and the employment of the garrison.

It is judged, that to be well provided with cannon, eight pieces should be allowed to each bastion. Therefore in a place of six bastions there ought to be 48 pieces.

As a town is never attacked on all sides, and there

Of Sieges. seeing what the enemy are about, and of opposing their attempts; but in the night nothing but a strong cannonading can guard against their enterprises. By day the troops fire from between baskets, sand-bags, or gabions, placed on the upper part of the parapet, to the end that being under cover they may take better aim at the enemy.

To know the quantity of powder requisite for a siege of any determined length, it will be necessary to know the quantity expended each day.

According to M. Vauban, of whom we have borrowed this whole detail, a pound of powder of 16 ounces may contain from 30 to 40 charges for common muskets, including their priming. Each soldier may fire from 60 to 80, and even to 90 charges, during the guard of 24 hours; and the quantity of powder for each man may be fixed at two pounds at a medium, for some will use more and some less.

Pounds.

We have supposed, that out of the 1000 men for the guard, there were but two-thirds in the front attacked, that is 666; now, allowing two pounds for each man, it amounts to

1332

For the two thirds of the bivouac, or those under arms placed near the attack; that is, 666 men, at the rate of half a pound each

333

For the 334 men of the guard at the post not attacked, at the rate of a quarter of a pound each

84

For 120 horse guards, at the rate of a quarter of a pound each

30

For 300 cannon-shot for each guard, each shot upon a medium rated at five pounds

1500

Observe that this estimate may be made exactly, when once the number of the pieces that are to be placed in the front attacked is determined; allowing nine pounds of powder to each piece of 24, six to each of 16, five to each of 12, three to each of 8, and two to each of four. Or the charge of every gun may be determined by half or a third part of the weight of the ball.

For 300 shot for wall guns, at two ounces each

38

Total 3317

Which is the quantity of powder expended each day, without including that of mortars, bombs, mines, grenades, &c.

Now, suppose a place is able to hold out 41 days, the quantity of powder, as laid before, for these 41 days, will be

135997

Besides, for 1200 thirteen-inch shells thrown during the siege, at the rate of 16 pounds each charge

19200

For 3000 eight-inch shells and lesser, at six pounds each

18000

For 6000 shots, with stone-mortars, at a pound and a half each

9000

For 3600 grenades, at four ounces each

9000

For mines and saggasses

8000

Powder burnt in the breaches

4000

For combustibles

3500

Allowance for waste and accidents

30000 Of Sieges.

For the surrender; that is, the quantity which ought to remain at the surrender

12000

And as it is advisable rather to have a superfluity of powder than want, to the above quantity we may farther add

21303

And reckon for the whole 270000 as that which expresses the quantity of powder with which the town ought to be provided against a siege; and, according to M. Vauban, this quantity may even be augmented to 280000.

After having given the estimate of powder, it is easy to give that of the shot, by taking it at two pounds for each pound of powder.

A great many more things are requisite in a town besieged.

Provision being as necessary as ammunition, in order to know the quantity that is requisite during a siege, it will be proper to observe, that every soldier is put upon the footing of a ration of bread each day, weighing one pound and a half. An ammunition-loaf, consisting of two rations, weighs three pounds or 48 ounces; but to give it this weight after it is baked, experience informs us, that it ought to weigh 56 ounces in dough, that is, the baking diminishes four ounces the ration.

A sack of ordinary flour, weighing 200 pounds, makes a hundred and fourscore rations. If the garrison consists of 3960 men, horse and foot, they will consume so many rations a day; which in 41 days will make 162360 rations, that is 902 sacks of flour. But though the garrison diminishes daily, this quantity of bread is not sufficient, because the officers have a greater number of rations, according to their rank; and besides, it is necessary to have provisions for those that attend the troops, as servants, artificers, nurses, surgeons, &c.

There must be likewise a certain quantity of provisions in the place when it surrenders; therefore it would not be too much to have two thousand sacks of flour in such a town as we have supposed, that is, garrisoned only by 3960 men.

There must also be a sufficient quantity of meat for the soldiers and officers. It is usual to allow a live ox and two sheep to a battalion for three days; which will produce a pound and a half of meat to each soldier, that is, half a pound each day. The other two days they have half a pound of bacon or salt beef, or a quarter of a pound of cheese with vegetables. In regard to the officers, they have meat given to them in proportion to their ration of bread.

As the most perfect fortifications cannot hold out long without the necessary ammunitions, too much care cannot be taken in regard to this article.

"The ancients, says Mr Folard, were accustomed to lay in a great store of provisions, when a place was threatened with a siege; a store sufficient not only for three or four months, but for three or four years at least. This they were induced to do for two reasons; the fear of being blockaded; and the inviolable law of defending themselves to the last extremity. The moderns take less precaution in respect to provisions, as well as to every thing else; they think it sufficient to

lay in a flock for three or four months, in towns of the greatest strength and importance; which is very wrong. I grant, indeed, (continues Mr Folard), that the law of holding out to the very last extremity, is looked upon as chimerical at present, and entirely left to the ancients: but it should be considered, that an enemy well acquainted with the state of things, will measure the strength of the place by the quantity of provisions contained therein; and making a calculation of the loss of men in the attack, together with the expence of a long siege, they will choose, if they are wise (and certainly they will gain by it in the end), to take it rather by a blockade than by a siege in form: at least they will be sure of becoming masters of it in three or four months through want of provisions; whereas a siege may last that time, if the garrison are obstinate. Such a town as Lille in Flanders, and as Bergues, both of which are cut of the line of communication of our frontier, cannot be too well stocked with provisions. A wise and experienced minister will victual them at least for eighteen months, because they may be blockaded. It is much the same in regard to Strasbourg and to Landau. The latter was never victualled for more than three or four months: how imprudent, therefore, must it be to lay siege to it, when it may be taken by a blockade almost as soon as by a siege, which is attended moreover with an infinite loss of brave men, and a monstrous expence."

These reflections of M. Folard are very solid; but circumstances will not always permit a place to be so well provided as one could wish.

When a governor finds that the enemy threatens to lay siege to a town under his care, and that the place is in want of the chief things necessary for a vigorous defence, he is to exert all his abilities, in order to remedy this inconvenience as much as possible. The greatest want of all is that of provisions; he must therefore endeavour to get a supply, both from the country and from the people of the town; which is to be distributed among the garrison with the greatest economy. The useless mouths should be all sent out, and an inquiry ought to be made after those who are suspected of having hoarded any corn; and upon paying them for it, or upon giving them security of payment, they should be obliged to deliver it up for the subsistence of the garrison.

Hitherto we have made no mention of the inhabitants; yet they may be rendered serviceable in contributing to ease the garrison. The governor should make use of such workmen who exercise handicraft trades for every thing relating to their respective branches; and those who are not artificers, should watch the fire that may be kindled by the shells and red-hot bullets; they ought likewise to transport the materials to the places assigned them; and even to work at the different retrrenchments which the governor should think fit to order in the town, provided however that they be not too much exposed to the fire of the besiegers. The priests and religious people may be of some use, in administering to the sick and wounded, and on other occasions, where there is nothing inconsistent with their character. The nuns and the poor women may be employed in washing the soldiers linen, in making lint, &c. The governor ought to regulate matters so, that every one shall contribute, as much as in him

lies, to the defence of the place. An article of the greatest importance, in regard to the inhabitants, is to oblige them to lay in a flock of provisions for six months. The same conduct may be used with respect to the religious houses; and those that are able should be obliged to make still a greater provision, which will be a resource to the garrison when their own flock is exhausted.

§ 2. Necessary preparations for maintaining a siege.

WHEN a town is threatened with a siege, the governor ought not only to take care to have a plentiful stock of ammunition and provisions, but moreover he should use all the precautions requisite for retarding the enemy's approaches, and rendering them more difficult and dangerous.

He ought therefore to leave nothing in the neighbourhood that may serve to cover the enemy; he should clear the adjacent country of all houses that are within reach of cannon-shot, and fill up, if possible, the caverns or hollow ways that may be concealed, or build some redoubts and other works under the protection of the place, by which they may be enfiladed. He ought to cut down all the trees; in a word, he should prevent the enemy's having any cover within reach of the cannon of the place: he should see that the fortifications be all in a good condition, and that the covert-way be well palisaded; in fine, he should cause arrows to be built on the salient angles of the glacis. Retrenchments may also be made in the re-entering places of arms of the covert-way, by raising a parapet within them, and parallel to their faces, with a small ditch before it. In a word, the governor ought to use all expedients possible to protract his defence, and to incommode the enemy. Nor should the galleries for the mines be forgotten: on the contrary, they ought to be begun betimes, and carried out into the country as far as the ground will permit; and chambers should be made under all the angles of the glacis. If there are any houses within the rampart which may obstruct the defence, the governor ought to see them demolished; and nothing should be left, either within or without, which can any way be of service to the besiegers. If there are new raised troops, care should be taken to discipline them well. "When the duke of Guise arrived at Metz, he found twelve companies of foot, which, as M. de Salignac relates in his account of the siege of that city, being new raised troops, he endeavoured to discipline and train them up to war: for which purpose, he gave orders that those who were upon guard, should march regularly from their quarters to the market-place before his house, where they drew up in battalia, and went through their exercise; and that the mulqueeters might be better used to their business, he made them fire at a mark."

The governor should also see that the hospitals be in a good condition, that the sick and wounded be taken care of, nor think it beneath his character to visit them himself, and to let the soldiers see how greatly he has their preservation at heart. This is the surest way to gain their confidence and affection, and to engage them to do their utmost towards defending the place.

As it is now the custom to throw a great number of shells into a town besieged, it is necessary to have

vaulted places under ground bomb-proof, where part of the garrison not on duty may rest in safety. They are not so much wanted in large cities, where there are always different quarters secure from the enemy's shells: but a small town is in every part exposed to the bombs; so that some places under ground are absolutely necessary for the garrison to take their rest, and to prevent the troops from being continually incommoded.

These subterraneous caverns are generally made in the gorges of the bastions, and sometimes under the rampart behind the curtains.

Where there are none of those subterraneous places, it will be necessary, as soon as the town is invested, to erect defences to shelter the men from the bombs; these are made of strong pieces of timber, laid sloping against the parts the least exposed, and they may be covered with thick planks laid in the same manner. The large houses should also be shored, that is, all the floors, from top to bottom, should be supported with strong upright timbers, and the upper floor covered with large beams laid across one another, and these again with earth, fascines, dung, &c. When they are thus fitted up, they may serve either for the accommodation of the troops or for hospitals, &c. But what deserves a more special care, is the powder-magazines. They ought to be bomb-proof; but as there are very few that can resist the shock of a great number of shells, they should therefore be covered with seven or eight feet thick of earth, and a layer of fascines, dung, and strong planks laid over them, so as to form a kind of roof. But if it should happen, either from their situation or height, that this cannot be done, than a range of large trees, well fastened together, must be laid over them, so as to diminish the shock of the shells. The windows of the powder-magazines should have no prospect towards the besiegers; and to prevent all accidents, nobody should be permitted to go in or out of the doors, but when the fire of the enemy is slackened.

When there are no powder-magazines in a town, it is very difficult to preserve the powder during a siege; all that can be done, is to distribute it in different places, as in cellars and caves made under the ramparts, or in gardens, &c. and to cover these places well with thick planks, earth, fascines, &c.

The mischief done by shells, consists not only in demolishing the buildings on which they fall, but likewise in setting fire to most places they fall upon; and when they are followed by red-hot balls, it is very difficult to hinder the town from being burnt. In order to remedy this evil, timely precautions should be taken, and the inhabitants employed in extinguishing the fire.

First of all, a great number of casks, filled with water, should be placed in the streets; and the soldiers and inhabitants ought to be divided into companies, to prevent the spreading of the flames. It will be proper to divide these into small bodies, and to allot different quarters to each of them, for extinguishing any fire that may happen to particular houses. By these means each corps, or company, will become answerable, in some measure, for the houses entrusted to their care, and use the utmost endeavours to preserve them. The pavements must also be taken up, and dung laid

in the streets, to prevent further mischief from the bursting of the shells.

§ 3. *Of the defence from the investing to the attack of the covert-way.*

WHEN the place is invested, and the besiegers begin to work upon the line of circumvallation, the governor ought not at first to fire upon the enemy's troops with the largest cannon, but with his small pieces only, to the end that the enemy, imagining there are no other guns in the place, may pitch their camp in full security out of the reach of those pieces, though there are much larger in the town: or else they may be deceived by half-loading the large ones, by which means they will not reach so far as when they have their full charge. As the enemy ought to pitch their camp as near as possible to the place, provided they are out of reach of cannon-shot, they will think themselves at a sufficient distance; but as soon as they are encamped, the garrison are to give them a full volley with their great guns, which will oblige them to decamp once more, and make them lose time.

If the adjacent country is divided by rivers, and the quarters of the camp are separated, the governor should fall upon those which are near at hand; but this must be done with great caution and prudence, for fear of having his men cut off, and losing part of his garrison.

As it is of importance to the besieged to know on which side the enemy intend to open their trenches, every endeavour should be used to discover it. The magazines of materials may perhaps direct them in this particular; because it is to be presumed, that the besiegers will place them near the attack; and therefore, when this spot is once known, the besieged should watch every night the opening of the trenches, in order to be ready to fire briskly on the workmen, which will greatly retard their operations.

While the besiegers are constructing the lines, their engineers spare no pains to get an exact knowledge of the adjacent ground, and to reconnoitre the fortifications, that they may form the plan of attack, which they will be sure to make on the weakest side. To prevent this, M. Goulan proposes the following scheme.

As soon as the town is invested, the governor should send 200 or 300 men every night, to that side which he knows to be the weakest, with orders to lie upon their faces, in the form of a semi-circle, of which the palisades of the covert-way may be considered as its diameter. These men should be divided into small parties, of three or four men each, at the distance of 20 or 30 paces from one another, so as to occupy a large tract of ground. All these different parties ought to agree upon a signal, to give notice when any body passes by them, and they should remain there in silence till day, without stirring, unless somebody happens to pass by; in which case, the first that sees them should rise, and give the signal to the rest, who are to do the same; then all drawing close together, and advancing to the palisades, they will take those who passed, as it were in a net, without any possibility of relief from their escort, who cannot be numerous enough to rescue them from the hands of 200 or 300 men, protected by the fire of the covert way. If the men who advance to reconnoitre the place, instead of passing

passing through the intervals, should fall in with some of these parties, and endeavour to get off, they must be fired upon: thus the enemy may be easily hindered from reconnoitering, and thereby acquiring a knowledge of the ground, or the side most proper to be attacked.

From the time the place is invested, the besieged should send every night small parties, of eight or ten men, commanded by a serjeant, with orders to lie upon their faces, all round the border of the glacis, and to listen carefully to every thing that passes. Whatever care the besiegers may take to open the trenches in silence, still it will be very difficult for this operation to be made, without such a motion as must be heard or perceived from the neighbourhood of the glacis. These small parties may even advance a little further, observing silence, and taking care not to be surprised by the parties which the enemy also may send out on that side, to watch whether there are any troops of the garrison ready to fall upon the workmen.

When the side on which the enemy open their trenches is known, the great pieces of ordnance are mounted on the rampart of the town *en barbette*, and the small ones on the covert-way, from whence they are to fire briskly upon the trenches. And to point more exactly, fire-balls are thrown from the mortars, which will give light enough to discover the workmen. Just at this time, the besieged should make the greatest fire against the enemy, because it is then they are most uncovered, and consequently most exposed. As the besieged cannot have their batteries ready till the second or third day after the opening of the trenches, during that time the guns may continue to fire *en barbette*; but it will hardly be possible to fire in that manner when the enemy's batteries are once erected. Mortars should likewise be used for throwing shell on the workmen and those employed on the batteries; in short, the best use should be made of the artillery, before the enemy are in a condition to silence it.

It is customary to make two or three attacks in order to divide the attention of the garrison; and of these, generally speaking, there is only one real: they must therefore endeavour to find out this real attack, and to use the utmost diligence in making good retrenchments, as well in the outworks, which the enemy must take before they can come to the body of the place, as in the gorge of the bastion of the front attacked. But to render these retrenchments strong and firm, they should have been begun and even finished before the opening of the trenches. A governor, who has a proper knowledge of fortification, ought to judge on which side a town is most accessible, and to presume that here the enemy will commence their attack; consequently he ought to think of every method of defence, the best adapted to retard the approaches, and dispute every inch of ground.

The besieged should so dispose their artillery at the beginning of a siege, as to enfilade the branches, and to direct their fire against the head of the trenches or the saps. This must be their principal effort; for it is by continually firing upon them, that they may reasonably hope to retard the works.

When the enemy have erected their batteries, it is very difficult for the besieged to maintain theirs, especially if they are placed on the produced faces of the pieces attacked. For as the cannon are continually

firing *à ricochet* against these faces, and it being difficult to guard against this firing, it will be very dangerous for the soldiers to remain there: all that can be done is to make some traverses, in order to diminish their effect; which is difficult indeed to compass, because the shot falling upon the traverses will bound between them. The besieged must not pretend to fire at the batteries of the besiegers, in order to dismount them; as the latter are more numerous, they must of consequence gain a superiority over those of the garrison, who by their obliquity would render their guns useless the remainder of the siege, since they must certainly be dismounted by those of the enemy. It is therefore more advisable not to persist in firing always from the same place against the enemy's batteries. By ceasing to fire from that part where the besiegers know there was a battery, they may be induced to think they have destroyed it, which will prevent their continuing to fire against it, and be a means of preserving the battery for future service. But in order to give them trouble, smaller guns may be placed in the outworks, on the faces of the bastions, from whence the trenches and batteries of the besiegers can be discovered; and they must often change place to perplex the enemy, who will find it very difficult to dismount those moving pieces. The besieged however must endeavour to repair the parapets destroyed by the enemy, and to take proper measures for firing again from thence, as soon as the besiegers have shifted their guns.

It is also advisable that the batteries of the besieged should not fire in salvo's, or all at a time: for it is well known, that the besiegers place soldiers in the trenches, to observe, through small loop-holes made with sand-bags in the parapet of the trench, when the batteries of the town are fired, and to give notice to those who are at work in the trenches, which way the guns are pointed, that they may put themselves under cover. If the besieged have only six pieces on a battery, and they fire them all at a time, the enemy have some moments of security to look over the parapet and to examine the ground where they intend to work and to conduct the trenches: but when the garrison vary their manner of firing, they give more uneasiness to those who are at work in the trenches, who will not be so ready to look over the parapet; which is ever dangerous, but especially when the trenches are brought within musket-shot of the place; though it be necessary, in order to view the situation of the ground towards which the works are to be directed.

§ 4. Of sallies.

A GARRISON that keep within a place, without making sallies, are, as the chevalier de Ville says, like those who are not concerned when their neighbour's house is on fire, and will not stir to extinguish it till it has reached their own. And indeed, as the besiegers continually carry on their approaches towards the town, it is of the utmost importance to endeavour, in time, to stop their progress; to which end, the making of sallies is extremely conducive, especially when they are well conducted, otherwise they would rather accelerate than retard the taking of the place.

How great soever the advantage of sallies may be,

yet they cannot be made in all sorts of fortified places; they are proper only when a garrison is numerous. A small garrison, although well stocked with all the kinds of necessary ammunitions for making a defence, and for holding out, ought to be very careful how they venture to make a fall. But a numerous garrison, not so well provided, ought to fatigue the enemy as much as possible by frequent sallies. The same measure ought to be followed, when a town is but ill fortified; the garrison should not shut themselves up so as to be obliged to surrender, as it were, without making much resistance. It is best in those cases to harass the enemy continually, to keep them at a distance as long as possible, and to use every stratagem and endeavour that may retard their approaching the glacis, and the taking of the covert-way. Thus it was that the marquis of Uxelles, afterwards marshal of France, behaved at the siege of Mentz in 1689. He defended this large and ill fortified town upwards of two months, with the help of a very brave garrison; but was obliged to capitulate for want of powder and ammunition, though he was still master of the covert-way, and even in some measure of the glacis: for the enemy had only one lodgment on the ridge of it; and even this, says M. de Feuquieres, the marquis suffered them to make, in order to have a pretence for capitulating, and that the besiegers might not suspect he surrendered for want of powder. In 1702, Keyserworth, a place but indifferently fortified, was defended nevertheless by numerous sallies, which rendered it a very dear acquisition to the enemy. In the like cases, sallies ought not to be neglected; but they must be made with great art and skill, to expect any success from them; for it is on these occasions, says M. Vauban, that the vigour, diligence, and good conduct of the governor, ought to appear in their full lustre.

When the besiegers are at a distance from the place, sallies are very dangerous, because the enemy may cut them off from the town with their horse; but when they have made their second parallel, and advanced the branches of the trenches towards the third parallel at the foot of the glacis, then is the time for the garrison to fall. They may even venture, though with great caution, when the besiegers are at work upon the second parallel, and before it is entirely finished; but the most favourable opportunity of falling, is when the besiegers are come to the third parallel, and want to make a lodgment on the glacis. Then there is no danger of being cut off; and the enemy may be surprised the more easily, as the garrison have it in their power to fall upon them all at once, and to throw them into confusion, without giving them time to recover themselves.

Sallies may be either great or small; the former ought to be with 500 or 600 men at least, or proportioned to the guard in the trenches; the latter are only with 10, 15, or 20 men.

The intent of great sallies should be to destroy a considerable part of the works of the besiegers, in order to oblige them to begin again; to nail up their guns; to retake some post which had been abandoned; and lastly, to obstruct the enemy's works as much as possible, and thereby retard the taking of the place.

In regard to small sallies, they serve for no other

end than to interrupt the workmen at the head of the trenches, so as to frighten them, and oblige them to run away. As it requires some time to bring them back, and to make them return to their work, this will occasion delay, and retard the approaches.

The best time for great sallies, is two hours before day-light, the troops being then fatigued and sleepy; therefore more easy to surprise, and less capable of making a vigorous resistance. And when it has rained very hard in the night, so that the guard in the trenches may be unable to make use of their fire-arms, this is also a favourable circumstance: in short, no opportunity should be neglected to surprise the enemy; for sallies seldom prove advantageous any other way. The following is the order which M. Vauban proposes to be observed.

There should be a detachment of 90 men drawn up, 30 in front, and three deep; to which must be added a fourth rank of 30 grenadiers. The three first ranks of this detachment should be armed with cuirasses: each soldier should have a sword and pistol at his belt, and a partizan, or long iron fork with a hook, in his hand. This detachment is to be followed by another of 180 men, 30 in front, and six deep; the first rank of these is to be armed as the former, with cuirasses and long weapons, the rest as usual. The first rank in this detachment is to make up the rear in the retreat. After this second detachment 200 workmen are to follow with proper tools to destroy the enemy's works, and several of these with combustibles to burn what they cannot otherwise destroy. Some of them are to be provided with long nails of steel, and of different magnitude, to spike the cannon; there must be some of a very large size, because the touch-holes happen frequently to be so very wide, that common nails will not fill them up exactly.

Besides the two detachments and workmen above mentioned, another body of 300 or 400 men should be ordered to support them, and to follow them slowly as far as the head of the trenches; where, if they find that those who went before them have no need of assistance, they should halt to be ready to act if occasion requires it. If the guard of the trenches should make a vigorous attack upon the fall, this detachment will support them, and jointly encounter the besiegers. If the latter are repulsed, which must be the case if the fall is not foreseen and expected, the workmen must set about demolishing the works, and filling up the trenches as fast as possible. These troops should also endeavour to penetrate as far as the batteries, in order to nail up the cannon, and to maintain themselves in the trenches long enough for the workmen to destroy great part of them. When they have done what they proposed, they retreat to the covert-way in good order; and if the enemy should be so imprudent as to pursue them as far as the glacis, they must be received with a brisk fire, as well from the cannon of the ramparts as from the troops in the covert-way.

In sallies, and generally in all actions performed by night, the soldiers should put something in their hats, as a white paper or handkerchief, to know one another in the dark. The troops designed for this purpose are drawn up in the place of arms within the town, or in the ditch if it be dry, or else in the covert-way. When they are to march out by different gates, some signal

signal should be agreed upon, that the troops may all move at the same time. If there are more attacks than one against the town, as generally is the case, then several sallies may be made at the same time upon these attacks. It might be proper to make a great noise on one side, in order to draw all the attention of the enemy that way; and while they are busy in the repulse, to act vigorously on the other side; for then they will meet with less resistance, and will be more capable of hurting the besiegers. However, as a sally which has not all the success that might be expected, ought not to discourage the garrison from repeating the attempt; so one that has been crowned with success, ought not to render them too confident, or inspire them with too great a contempt for the enemy. The mistakes the latter may have committed, will rouse their attention, and put them upon their guard. We ought ever to suppose, that they will do all that we should do, were we in their place, and that they will take proper measures to remove every obstacle that may oppose them.

Hitherto we have taken no notice of the use of cavalry in sallies; and yet on some occasions they may be of service, which is when the besiegers are at a distance from the place. In this case, two detachments of horse are ordered to the right and left to support the sallies, and to hinder the enemy's horse from falling upon them. These detachments serve also to protect their retreat, and to prevent their being cut off; but when the besiegers have finished their third parallel, the sallies are then made with foot only, and should, as we have above observed, be often repeated, provided the garrison is numerous enough to dispute every inch of ground with the enemy.

As soon as the troops are returned from the sally, fire-balls should be thrown into the trenches, to discourage the workmen who are employed in repairing the mischief that has been done, and are at that time in some measure uncovered. The fire of the place well served at this juncture, must kill a great many of the enemy. So far relates to great sallies.

The small sallies, which are intended merely to disturb the besiegers without being able to do them much hurt, are conducted in the manner following. The governor orders out parties of 10, 15, or 20 stout men only, as hath been already observed, who are to advance softly to the head of the trenches, and to jump into them quickly, making a great noise, and throwing grenades; after which they are to retire with all expedition: the alarm which they will occasion is sufficient to make the workmen take to their heels, who desire nothing better than to have a specious pretence, as M. Goulon observes, to run away upon the least alarm; and it is impossible to prevent it, or to bring them back the same night, so that the besiegers must lose all this time. It says the same author, the besiegers become accustomed to these little sallies, so as to grow secure and take no notice of them, the besieged observing this must make one in good earnest, which coming unexpected, will easily overturn the workmen and the troops that cover them; after which they may retire without fighting, lest they should draw the whole guard of the trenches upon their backs.

§ 5. Of the defence of the glacis and the covert-way.

BESIDES the sallies which retard the lodgment of

the besiegers on the glacis, mines may increase the difficulty of approaching. We have already taken notice of these in the section of *Attack*; we have only to observe here in general, that the besieged must make the best use of them possible, in order to blow up the enemy as often as the ground will permit; this is the surest way to keep the besiegers in awe, and to oblige them to advance with the greatest circumspection.

Besides the galleries and mines which ought to be under the glacis, the besieged may also lay opposite to its angles large planks, stuck full of very long nails, with the points upwards, to incommode the enemy in passing over the glacis. These planks ought to be strongly fixed, to prevent their being easily taken away. The burying of caissons in the glacis is also productive of a good effect. These are small chests, two or three feet long, and a foot and a half broad, filled with powder; they are fired at any time by a train conveyed in a wooden trough into the covert-way: they ought never to be placed nearer than six or eight feet to the inside of the covert-way, lest they should do any damage to the troops that defend this post. Sometimes shells are put into these caissons, and then they produce a still greater effect.

When the enemy endeavour to make a lodgment on the glacis, the garrison must repeat their sallies with greater vigour; which may be done without any inconvenience, because of the facility of retreating. When the troops are returned from the sally, fire is set to the chambers and caissons, which will greatly disconcert the besiegers. If the chambers are well disposed, they must hurt their lodgments prodigiously; and as soon as they are sprung, the besieged may fall upon the enemy, this being a favourable opportunity for surprising them in disorder, and consequently of destroying part of their works. This manner of proceeding should be often repeated, in order to fatigue the besiegers, and to retard the taking of the covert-way.

When the enemy are ready to storm it, the garrison must prepare to give them a warm reception. The difficulty of making a lodgment in the covert-way may be increased by a double row of palisades: the second should be lower than the first, to the end that the enemy may not perceive them. These two rows ought to be at the distance of four or five feet from one another, to prevent the besiegers from jumping over them into the covert-way. Between them may be made a small ditch; most of the enemy's grenades will fall into it, and cause less mischief to the troops. Care must be taken to make strong retranchments in the places of arms, either by raising a parapet within-side, and parallel to its faces, with a small ditch at the foot of it, or by simple rows of palisades, which will hinder the enemy from forcing their way so easily as they would otherwise be capable of doing. In each place of arms there should be one or two barrels of powder, with balls and small-arms necessary for the defence of the covert-way.

All the batteries must be got ready to fire with the utmost briskness upon the enemy, when they are at work upon their lodgment. Every part of the place that looks into the covert-way ought to be lined with troops, who are to fire upon the besiegers: but there ought to be no troops in the parts opposite to the

places of arms, that the troops posted there may not be hurt by the fire from the body of the place.

The garrison should endeavour to be informed by deserters at what time the enemy intend to make their attack; the motions of the latter may be also observed by persons posted on steeples; and as soon as the troops are perceived to make an extraordinary motion, and the trenches to be filled more than usual, this is a sign that they are going to attack. The vicinity of the enemy's works may also enable the besieged to judge of their forwardness; and all this together direct them to take such measures as are proper for giving a warm reception to the besiegers.

As soon as the garrison perceive that the enemy are marching out of their trenches, they should keep firing upon them continually with great and small arms, from all the works facing the attack. This will destroy a great many of their men before they can reach the palisades; the two rows of which in the covert-way will prevent their jumping into it directly. They will be under a necessity of breaking them successively with hatchets; and while this is doing, a general discharge is to be made from the batteries of the town, which will do great execution. When, after a vigorous resistance, the garrison find themselves hard pressed by the enemy, they may abandon the covert-way, and retire into the places of arms; and while the besiegers are working upon their lodgment, they will be exposed to the fire of the place, which takes them in front; and to that of the places of arms, by which they are taken in flank; so that their loss must increase considerably. If they have mines ready, as we suppose they have, they must spring them, after having fullered the enemy to work for some time upon their lodgments; and after having kept firing against them continually with great and small arms, then immediately they should make a strong sally from the places of arms, and taking advantage of the disorder into which the besiegers must inevitably be thrown, they will oblige them to abandon the covert-way.

If there is no possibility of hindering the enemy from making lodgments on the crest of the covert-way, or, which is the same thing, on the ridge of the glacis, the besieged must endeavour to retard them, and to dispute as long as possible their taking possession of the places of arms. On this occasion bougasies are employed with success, and should be repeated several times if the ground will permit. When the besiegers have once completed their lodgment, and supported it in a proper manner, they want nothing further than a little time to extend themselves, and to become masters of the covert-way. The obtuseness of the besieged can only retard, but not absolutely hinder the taking of this outwork.

These kinds of attacks sword in hand are extremely bloody, as we have formerly observed; nor are they always attended with success. The allies attacked in this manner the covert-way of Lisle, and lost upwards of 2000 killed and 2667 wounded; and after all they could only make a lodgment on two salient angles, which were not defended by so great a number of troops as the rest. In the same manner did marshal Villars attack the covert-way of Friburg in 1713; and indeed he made himself master of it through the extraordinary bravery of the troops: but this exploit

cost him 1500 men killed and wounded. The single regiment of Alsace lost four captains of grenadiers, and 643 men killed and wounded. The method of proceeding by sap is infinitely less bloody and more sure; besides, according to M. Vauban, it can hardly retard the taking of the covert-way above four or five days.

Let us suppose at present that the enemy resolve to approach the covert-way by sap, and that they have raised cavaliers in the trenches to plunge into this outwork, the besieged must strive to retard this operation by every stratagem imaginable; for when the cavaliers are once constructed, it will be very dangerous to abide any longer in the covert-way. They must stop the besiegers at every step with mines; they must harass them with a constant discharge of fire-arms, and dispute every inch of ground, defending themselves behind every traverse, and in the places of arms, as well as they can, without running too great a risk of having their retreat cut off.

§ 6. *Of the defence of the passage over the ditch before the half-moon.*

THE enemy having made themselves masters of the covert-way, and perfected all their lodgments, will erect their batteries for making a breach, and prepare for the descent into the ditch. All this while the besieged must keep firing both with their great and small arms, in order to incommode the enemy in the construction of their batteries. If the ditch is dry, the soldiers may mount with ladders along the counterscarp, and from thence throw grenades into the enemy's works; and when they cover themselves in the covert-way with sand-bags, gabions, &c. against the fire of the place, these very soldiers should, with great sap-hooks, pull down part of them, and afterwards jump nimbly into the ditch, leaving the enemy exposed to the fire of the town while they are putting their materials again into order. Mines may be likewise used here with great advantage; they furnish various means to harass the enemy, to obstruct their works, and to make them lose time and men.

The batteries of the besiegers being destroyed by mines made under them, must oblige them to lose a great deal of time in repairing them, and in endeavouring to make themselves masters of the mines, otherwise they can never be secure. When the besieged have blown up the batteries that were to open the breach, they must make good use of the time which the enemy will spend in repairing them, and strive to perfect the retrenchments, which should have been set about at the commencement of the siege, in the gorge of the half-moon, and in those of the battions of the front attacked.

At the siege of Turin, in 1706, the enemy several times blew up the French batteries in the covert-way; so that by this, and other stratagems, they found means to prolong the siege, and gave time to prince Eugene to march to their assistance, who relieved the town, after he had forced the lines behind which the French army was encamped.

The mines for blowing up the batteries of the covert-way, may be disposed in such a manner as to tumble the guns into the ditch, as may be seen in the course of mathematics by M. Belidor; who performed it with success at the academy of La Fere.

It is certainly a great advantage thus to be able to become masters of the cannon of the besiegers, and to oblige them to erect new batteries, which must take them up a considerable time. A doubt here may arise, whether if these batteries are opposite to that part where the enemy intend to pass the ditch, this would not be helping to fill it up, should the besieged blow up the guns: but this inconvenience is of no great consequence, especially as it may easily be remedied, by clearing away the rubbish of the mine which tumbles into the ditch along with the battery.

As the besiegers work at the descent into the ditch at the same time that they are preparing their batteries, the besieged must think of retarding both these operations also at the same time. If the descent into the ditch is made under ground, miners should be employed to interrupt the work; and if the ditch is dry, small detachments, as M. Goulou observes, of five or six men, may be placed near the counterscarp, to watch the moment that the enemy break through it, and immediately to fire into the gallery: this discharge will either kill or frighten the miners; and at least will retard the works. Those who have fired, should retire on each side the opening to load their arms again, which may be repeated several times. Fire-balls and grenades may be likewise thrown into this opening, which will oblige the sappers to retreat. The more endeavours are used to interrupt the works of the besiegers, the more the surrender of the place will be retarded.

If the ditch is filled with water, the same operations may likewise be performed with small boats made on purpose; and to cover these boats a kind of parapet should be also raised by means of strong boards, with holes to fire through upon the soldiers, who upon opening the gallery will throw fascines into the ditch. At the siege of Lille, marshal Boufflers contrived some of this kind of boats to retard the passage over the ditch, before the grand lunettes or tenaillons in the front attacked, and that before the half-moon.

When the enemy make their opening into the dry ditch, they must be opposed with a strong fire, as well from the face of the bastion which flanks the ditch before the half-moon, as from the place of arms or traverse, which ought to be constructed the whole breadth of the ditch, in order to strengthen the defence. By night small sallies should be made from this place of arms, with a view to interrupt the passage over the ditch, and to retard, as much as possible, the fixing of the miner.

There are two ways of passing the dry ditch, and of bringing the miner to the foot of the revetment, which he is to enter. The first consists in making a gallery six feet wide, with a double row of barrels. These must be filled with sand-bags, and so must the spaces between them, in order to render the passage of the gallery more safe; and that there may be a shelter from fire-works, strong planks are laid over it, and these again are covered with raw hides, or with earth and dung. This gallery is continued within three or four feet of the revetment; and in this space a good epaulement is raised with sand-bags to cover the miner on the side exposed to the place. In regard to the other side, it is of no use to stop it up; nay, it serves for an opening to fill the ditch with the earth dug out of the

galleries, which the miners are making in the rampart of the work attacked. It is easy to oppose the progress of this gallery with a continual fire, and with several lesser works constructed within the ditch.

The other way, which, as we have already seen in treating of the attack, consists only in getting to the foot of the breach by sap, with an epaulement on the side exposed to the place, and which may be covered, in order to protect the passage from the fire-works and grenades of the besieged. But this sap may be retarded by sallies; the besieged may likewise steal away the earth by night from the epaulements, and endeavour with hooks, &c. to displace the gabions and fascines.

If the ditch is filled with water, the besieged must interrupt the enemy's bridge with a continual fire from their great and small guns, as well as with grenades and shells, if they are in a condition to fire upon the bridge and its epaulement. If the water has a strong current, they must open sluices in order to break down the bridge, or at least to carry away the fascines. They should also attempt to set fire to it, with artificial works prepared for this purpose. They may likewise approach the epaulement in the night, and draw away the fascines with hooks. They may even throw anchors upon it; and by means of caplans placed in those parts which flank the ditch, they may draw these anchors with cords fastened to them, and tumble part of the epaulement into the ditch. In short, every expedient must be tried that may possibly retard the enemy's approaches: for when once they have perfected their bridge, they will soon be masters of the outwork to which that bridge leads, whatever precaution the garrison may take to defend the breach; because, as the besiegers can always pour in fresh men to supply the room of those that are lost in the attack, they must at length surmount all opposition of the besieged,

§ 7. Of the defence of the half-moon.

WHILE the enemy are effecting the passage over the ditch, besides the difficulties that are raised to retard the work, all proper precautions should be used to defend the breach, and prevent the taking of the half-moon. For this purpose guns are placed in all the works from which the breach may be seen; and they should be placed on carriages or on pieces of wood, as the garrison find most commodious, of least hindrance to the defence, and productive of the best effect.

If the half-moon has no reduit, as here we suppose it has none, the retranchments, which ought to have been made there, must be put into good condition; a row of palisades must be placed before it, in order to stop the first fury of the enemy after they have made themselves masters of the breach; in a word, the besieged must prepare to dispute every inch of ground, and to retire from the half-moon into the town, when they find themselves hard pressed and no longer able to maintain that post.

The enemy may be likewise hindered from mounting the breach, if they are ready to mount before the garrison are prepared to receive them, by throwing a great quantity of combustibles at the foot of the breach. At Turin, the garrison by this means retarded the French several days from taking the works in the front attacked. When the enemy present themselves at the foot.

When the besiegers have surmounted all these obstacles, and at last have got possession of the breach, the mines are sprung in order to blow them up, and chevaux-de-frize are placed along the whole breadth of the breach. The troops post themselves behind, and continue to make a vigorous fire upon the besiegers while they are using their utmost endeavours to penetrate into the half-moon; and when they begin to force their way, the first rank of men that defend it, being armed with piquets or halberds, and supported by the other troops, ought to fall upon the enemy, and cut them in pieces. But if the besiegers at length by dint of numbers should drive the garrison from the breach, the latter ought to retire into the retrenchment, and from thence make a very brisk firing; and when they find that this is also upon the point of being forced, then they are to withdraw their cannon, and whatever ammunition they may have, into the place; and last of all, if they have any mines under that spot, they must spring them as they retire, in order to do all the mischief and to create all the confusion they can to the besiegers.

Sometimes it shall happen that the enemy, after having made themselves masters of the half-moon, omit to leave a sufficient number of troops to guard the lodgment, upon a presumption that the besieged will not attempt to retake it. Whenever they show a confidence of this kind, a strong body of the garrison should return in the night and storm this work, either by the gorge, or by some other part. There are great odds, but such a vigorous and sudden surprise will be productive of a very good effect; at least there is no great risk in trying, if the strength of the garrison will

permit; and should they succeed, the taking of the town will be retarded several days.

Here we have supposed that the enemy are resolved to storm the half-moon; but if they should attempt to get possession of it by means of saps, in that case the workmen must be continually harassed by blowing up of mines, and kept as long as possible from the breach, by means of fire-works of all kinds. When they begin to make a lodgment in the breach, then the besieged should fall upon them briskly, and destroy the lodgment; in short, every artifice imaginable should be used to retard their progress.

This last method is less bold than the other; but on the other hand, it may be very tedious, when the besieged spare no pains to disturb the enemy's sappers and miners.

One thing that greatly deserves attention, and may render it very difficult for the besiegers to mount to the assault, or to lodge themselves in the breach by means of saps, is to clear away the rubbish in the breach. In a dry ditch this may be easily done; but in a wet one, the thing is more difficult: on the other hand, in the latter case the breach is more easy to defend than in the former; because as the enemy cannot come to the foot of it but by the bridge of fascines, which is made in the ditch, and is seldom above 10 or 12 feet wide, they cannot of course present themselves with so large a front before the breach as in a dry ditch; consequently the garrison must find it much easier to repel them.

§ 8. *Of the defence of the passage over the ditch before the bastion.*

At the same time that the enemy are carrying on the attacks of the half-moon, they work at the passage over the ditch before the bastion. What has been said in regard to the defence of the ditch before the half-moon, may be applied on this occasion; we have only to add, that when this ditch is dry, the caponier will be of great use to fire upon the enemy in their passage over the ditch, and to fall from thence in order to destroy their works. The besieged must fire into the opening of the descent, as we have already observed in regard to the ditch before the half-moon; even a kind of retrenchment ought to be raised opposite to that part where it appears that the opening will be made, in order to retard it; some small cannon should be also charged with cartridge-shot, to fire into the hole: and last of all, that the soldiers in the retrenchment may be sheltered from the combustibles which the besiegers will throw upon them from the upper part of the covert-way, the retrenchment should be covered with strong planks. By proceeding in the same manner opposite to all the descents, their passage may be greatly retarded. Different retrenchments may be also made in the ditch, in order to dispute the ground inch by inch. There should likewise be frequent sallies, which cannot but be productive of a very good effect; and the horse may be employed without much danger on this occasion, because they have the extent of the ditch to retire into.

If the ditch is wet, it must be defended in the same manner as that before the half-moon: here only we shall add, that if there is a tenaille opposite to the curtain of the front attacked, the fire from thence will greatly

Fig. 2.
WEAVING Loom &c

Sieges. greatly annoy those who are employed in filling up the ditch. Besides, the boats by which we observed that the enemy might be incommoded in the passage over the ditch, the besieged may likewise have recourse to a kind of floats, made with double joists, at the end of which are fastened empty barrels, to prevent their sinking too deep in the water; and these floats should be loaded with shells, barrels of gunpowder, fascines, pitch and tar; and in short, with all sorts of combustibles proper for setting fire to the bridge, and to the enemy's epaulement: these are brought forward and fastened to the epaulement, and afterwards they are set on fire with a match, or with tow laid amidst the combustibles. Doubtless there are many other stratagems to interrupt the passage over the ditch; what we have mentioned here, is only to give some idea of it. An able governor may hit upon several other expedients to dispute this passage, which indeed is the most brilliant part of the whole defence. But in order to hold out to the very last, he should be able to withstand the assault upon the body of the place; which may be done without any great inconveniency, when there are good retrenchments in the gorges of the bastions, as we have supposed in this Treatise.

When there are dikes or sluices, by means of which the ditch may be filled with water at any time, every art must be tried to defend it while it is dry; and when all the defences are exhausted, then the water is let in, and the enemy will be obliged to begin their work again.

§ 9. *Of the defence of the bastions in the front attacked.*

HERE the reader must recollect what has been said in regard to the defence of the breach in the half-moon. The defence of the bastions is more easy, because it is not so difficult to retreat from thence, by means of the retrenchment; and this retrenchment should be larger and more spacious than that of the half-moon, and more difficult to force.

Besides all the precautions we have been mentioning, as mines under the breaches, within the bastions, &c. the besieged should also mount several pieces of cannon on the breach, charged with cartridge-shot, and pointed downwards, so as to be able to sweep the whole surface of the ground, on which the enemy must form in order to march to the assault. Care must also be taken, lest the enemy, discouraged with the difficulty of storming the breach, do attempt to scale the bastion, as hath been practised several times, and particularly by the duke de Noailles, marshal of France, at the siege of Gironne, in 1712, as mentioned by M. Folard, in his Commentary on Polybius, and in the preceding Section of *Attack*. The way to guard against this attempt, is to place along the parapet of the works that may be insulted, large pieces of timber, which are to be tumbled upon the ladders as soon as the enemy offer to mount. They should also have loaded shells all along the rampart, fastened to chains, and to let down towards the middle of the ladders, where they will burst and kill those who are mounted. They should likewise be provided with combustibles of different kinds, to throw upon the besiegers, and to keep them off from the foot of the revetement. When the garrison are well prepared against this attempt, it will be very difficult for the enemy to succeed.

VOL. X.

The entrance of the bastion may likewise be defended, by making a ditch in the upper part of the breach, and filling it with all sorts of combustible matter. This will form an impenetrable barrier against the enemy, at least for some days; which time is to be employed in strengthening the retrenchments, and throwing up others, one behind another, if the ground will permit, and it be resolved to defend the place to the last extremity. Though it is usual for the enemy to force their way into the town by the bastion, and therefore the principal retrenchments for defending the entrance of the place should be raised in this part; yet it is proper not to neglect the curtain. The enemy may be apprised of these retrenchments, and as it is not the practice to make any behind the curtain, they may take it into their heads to batter it in breach, and to construct a bridge in the ditch before it, in order to penetrate into the town. Thus did prince Eugene act at Liffes; as the back part of the curtain was open, the place was obliged to capitulate. The breaches may likewise be defended by repairing them with large trees laid across one another, the branches pointed towards the enemy. Cannon will make no great impression on this kind of wall; which was the principal defence of the ancients when a breach was made.

When the besiegers have triumphed over all these obstacles, so as to be masters of the breach, and to extend their lodgments on the bastion; then it is no longer possible to defer capitulating, unless there are several retrenchments one behind the other. For in that case, the besieged, if they think proper, may defend themselves to the very last. At Osend the garrison held out till they were forced into the very heart of the town; and the inhabitants of Barcelona did the same in 1713: but this desperate defence is very rare. Few governors defer surrendering till reduced to the last extremity; they choose to preserve the garrison, and to save the town from being plundered, which would be the case, according to the laws of war, if it was taken by storm. When the enemy insist upon the garrison's surrendering prisoners of war, I should think this condition ought not to be submitted to, till they are reduced to the last extremity; but it belongs to the generals, and the commanding officers in fortified towns, to behave on this article as their own prudence shall direct, and according to the orders they may have received. A discussion of this kind is neither within our province, nor the nature of this work.

§ 10. *Of precautions to be used against the surprising of towns, scaladers, sudden attacks, &c.*

THE right way to prevent surprises, is to think that the enemy have a design upon the town, and to use all the precautions possible in order to frustrate their designs. With this view a governor should put the fortifications into a good state of defence, should see that the several posts, as well those that are accessible as those that are inaccessible, be well guarded, that parties be sent to range in all the principal avenues of the place; in a word, he should most exactly observe whatever is prescribed in the military ordinances concerning the guard of towns, the opening and shutting of gates, &c. We shall make no mention of any of these particulars, because they are so minutely described in the ordinances; and, moreover, a very short

Of Sieges. stay in a garrison is sufficient for learning every thing that may relate to the daily and customary duty, as well for the safety of the town, as for the preserving peace and good order among the inhabitants, and for preventing any strangers or suspected persons from entering the place, &c.

We shall only observe, that when a fortress is situated upon a river, care should be taken to have boats in the night, filled with soldiers, both above and below the town, to hinder any body from getting in that way undiscovered. If the ditches are filled with water, in frosty weather the ice should be broke every day; in short, nothing should be neglected that tends to secure the place against any enterprise either from within or without.

But chiefly on fair or market days this vigilance should be exerted; the guards ought to be doubled at all the gates, and the garrison should be disposed in such a manner as to be ready to fly to their arms upon the first beat of drum; care should be also taken to make the cavalry mount on horseback, ready to act in all events. By using these precautions, it will be very difficult for the enemy to surprize the town; nay, the consequence may be, that hearing of the exact discipline observed by the garrison, they will relinquish their design; for surprizes seldom succeed, except through neglect of military duty, and too great security in the governor.

With regard to precautions against escalades, they consist in having small parties continually about the avenues of the place, in order to be better informed of the enemy's motions, and to keep a patrol all night, to see that nobody shall enter the ditch unperceived. A cuvette may be likewise dug within the ditch, and palisades planted within some distance of the wall, to hinder the enemy from fixing their ladders to it; the flanks of the bastions should be furnished with cannon, charged with cartridge shot, with balls of a quarter of a pound weight, or with pieces of old iron, to fire upon those who should attempt to scale the place opposite the curtains; in the corps de gardes, within reach of the rampart, a provision should be made of halberts, with all other offensive weapons fit for repelling the enemy when they appear on the top of the ladder, and for driving them into the ditch; the ramparts should be stocked with a great quantity of cylindrical timber, to roll down upon the ladders, and those that are upon them; and if the garrison are not so numerous as to be able to cover the whole ramparts, they should fix chevaux-de-frize, or something else, to the upper part of the parapet, which will hinder the enemy from getting over, in order to jump upon the rampart. There ought also to be a stock of shells and grenades all loaded upon the walls, in order to roll them down into the ditch upon the enemy. There should likewise be fire-works ready to throw upon them, as fascines done over with pitch and tar, powder-barrels, fire-pots, &c. a great number of fire-balls should be also hung in the ditch in order to give light, and that the cannon of the place may do good execution upon those who are got into it; the ditch should likewise be filled with crows-feet, or little holes dug and covered with hurdles and earth, so that the enemy shall not perceive them, but tumble into them: in the middle of these little ditches there should be a palisade,

or some long iron spikes, ranged in such a manner as to run those through that shall fall upon them. All these precautions will render the enemy's attempt very difficult; for, as we have observed several times in the course of this work, when men are prepared to defend themselves against a scalade, it seldom succeeds. Neither are the gates to be neglected; the enemy will not fail to try to fix a petard to them, while the troops are endeavouring to make themselves masters of the rampart. Soldiers must be placed in a convenient situation for firing on the person that fixes the petard: in all events the gates must be strengthened within side; and large trees must be got ready to debar the enemy from entering the town, should they be able to break open the gate; the whole as hath been mentioned in the attack of small towns, castles, &c.

At the first alarm of an attack, all the troops ought to run to the place assigned them, in order to be led from thence to the ramparts. With regard to the cavalry, they ought also to mount on horseback, and to divide themselves into several small bodies, which are to be at the foot of the rampart, ready at all events to charge the enemy, should they find means to penetrate by some way or other into the town.

If the enemy make several attacks at the same time, it will not be proper to quit those parts where they do not show themselves; this perhaps is a feint only to draw the troops from the side which they really intend to attack; therefore the garrison should be equally on their guard on all sides, and leave no posts naked, unless the enemy have forced their way into the town; then indeed the business is to charge them vigorously, in order to oblige them to retire.

Upon the whole, it is easy to withstand a scalade when there is no surprize; and therefore it rarely happens that a governor, who takes the necessary precautions against any such accidents, will lose a town by this kind of attack.

A scalade may be attempted in the day as well as by night; the latter indeed is more favourable to the assailants, yet they will not succeed a whit the better, if they find that the garrison are prepared to receive them, agreeable to what we have already mentioned.

There remains only to mention a word or two in regard to accelerated sieges; which is, that a governor will not be exposed to this sort of siege, if he takes the proper precautions to be informed of the steps and approaches of the besiegers.

If the enemy pretend to carry on a siege in form, and at the same time accelerate their approaches on one side of the place; the garrison must fall vigorously upon them, and spare no pains to drive them out of what works they have seized upon. One may suspect their design, if it appears that they do not make their attack on the side of the town where naturally they ought to make it, if they want to become masters of the place with greater ease; and then the besieged should double their guard on that side. In general, there should be a constant attention to all the fronts of the place, and they should be all equally guarded, till it appears clearly by the enemy's works on which side they form their attack, and which way they direct their works; neither are the other sides to be neglected, notwithstanding all this, lest the enemy should lay hold of this opportunity to attack them. It is always to be

be supposed that they are informed of every thing that passes within the town, either by their spies, or by deserters; for which reason the post that seems least accessible ought not to be neglected.

§ 11. Of capitulations.

THE capitulation being the last transaction, both in the attack and defence of a town, this seems to be the most natural place for speaking of it, as it seems to be the most proper subject for terminating this work.

When the governor, who defends a town, finds himself reduced to the last extremity, or is ordered by his court to surrender, with a view of obtaining better conditions of the enemy, both for the town and garrison, he orders the *chamade* to be beat. For this purpose one or more drummers are directed to beat their drums on the rampart, on the side next to the attack, to give notice to the besiegers that the governor has something to propose to them; one or more white colours are likewise hung out for the same purpose, and one of them remains either on the rampart or on the breach during the time of negotiation. The same is practised in demanding a suspension of arms, after a very violent attack, to bury the dead, carry off the wounded, &c.

As soon as the *chamade* is beat, the firing ceases on both sides, and the governor sends some officers of distinction to the general who commands the siege, with the conditions on which it is proposed to surrender. As a security, or as hostages for those officers, the besiegers send at the same time the same number into the town: if the governor's proposals are not agreeable to the commander of the besieging army, he rejects them, and mentions what terms he is willing to grant. Generally speaking he threatens the governor to allow him no conditions at all, if he does not determine to surrender quickly; for instance, when the passage over the ditch of the place is finished, or batteries are erected opposite the flanks, &c. If the besieged find the conditions too hard, the hostages are restored, and the drums are beat again upon the rampart, to make every body withdraw before hostilities are renewed, which is done very soon after. It is to be observed, that during the negotiation they ought to be quiet on both sides, and by no means should go on with the operations of the siege. The governor ought during this time to be upon his guard, for fear of being surpris'd by stratagem; which might expose him to the discretion of the besieger.

Suppose that the terms of capitulation are agreed upon, two or three of the principal officers of the garrison are sent as hostages to the enemy; and the general of the besieging army sends back the same number, and of equal degree, as a security for fulfilling the capitulation. When the besieged have executed every thing they promised, their hostages are returned; and when the besiegers have fulfilled their engagements, their hostages are returned also.

The conditions insisted upon by the besieged must vary according to the different circumstances and situations in which they find themselves. The following are the most usual.

1. That the garrison shall march out through the breach, with arms, baggage, horses, drums beating,

matches lighted at both ends, colours flying, a certain number of cannon and mortars, with their appurtenances, spare carriages, ammunition for a certain number of charges, to be conducted in safety to the town agreed upon, and which is generally the nearest of those that belong to the besieged. It must be observed to insert by the shortest road; or the road by which the garrison want to be conducted, is particularly mentioned. When the garrison have several days to march before they can reach the place appointed, it is required that the troops should be allowed provisions for four or five days, according to the time they are to be upon the road.

2. That the same evening, or at a certain hour the next day, one of the gates of the town shall be delivered up to the besiegers, and the garrison are to march out a day or two after, according as both parties have agreed.

3. The besiegers shall furnish a certain number of covered waggons, that is, which are not to be inspected, besides waggons for removing the sick and wounded, that are in a condition of being removed; and in general all the carriages necessary for the baggage of the garrison, and for the artillery allowed by the capitulation.

4. The sick and wounded, who are obliged to stay behind, shall have liberty to leave the town, with every thing belonging to them, as soon as they are in a condition so to do; and in the mean time they shall be furnished with lodgings *gratis*, or otherwise.

5. No indemnification shall be required of the besieged, for houses taken from the town's people, nor for houses burnt or demolished during the siege.

6. The governor, the general officers, all the officers belonging to the troops, the troops themselves, and in general every one in the king's service, shall be suffered to leave the place, without being subject to any act of reprisal, of what nature soever, and under any pretext whatsoever.

7. If those to whom the town is surrendered, are of a different religion from that of the inhabitants, it must be mentioned in the capitulation, that the inhabitants shall be maintained in the exercise of their religion.

8. The inhabitants shall also be maintained in all their rights and privileges.

9. Those who are willing to quit the town, shall be at liberty to go and settle where they please, with all their effects. It is also stipulated sometimes, and indeed ought to be stipulated, whenever there is any apprehension that the enemy will behave with rigour to the inhabitants, for any partiality they may have shown during the siege to the prince whose subjects they cease to be, that they shall not be disturbed or molested for any thing they may have done before or during the siege.

10. It is also inserted in the capitulation, that all the powder and ammunition remaining in the place shall be delivered up, and the loaded mines are likewise discovered.

11. The prisoners made on both sides during the siege shall be restored.

It must be observed, that a place should have provision and ammunition at least for three days, to be intitled to a capitulation, without which they are made prisoners of war. But if the besiegers are unacquaint-

ed with it, and the capitulation is signed, it would not be fair to make the garrison prisoners of war, upon discovering the want of ammunition.

When the besiegers refuse to grant a capitulation, unless the garrison surrender themselves prisoners of war, and the latter are under the necessity of submitting to this cruel law, they endeavour to soften it as much as possible: and therefore it is commonly agreed,

1. That the governor, and the principal officers, shall keep their swords, pistols, baggage, &c.

2. That the subaltern officers, below a captain, shall have only their swords, with their baggage.

3. That the soldiers shall be neither rifled, nor separated from their regiments.

4. That the garrison shall be conducted to such a place, to remain prisoners of war.

5. That the principal officers shall have leave for two or three months to go and settle their affairs.

6. That when the garrison quit a place, it shall not be allowed to decoy the soldiers, in order to make them desert from their regiments.

When the capitulation is entirely settled, an officer of artillery from the besiegers enters the town, to take an inventory of all the artillery and ammunition remaining in the place, in conjunction with an officer of artillery from the garrison. A commissary of stores enters likewise to take an account of the provisions.

When a governor finds that he must surrender, and that there are considerable magazines of ammunition and provisions, he should destroy most of them before he offers to surrender, to the end that there may remain no more in the place than what is necessary for a capitulation, and that the enemy may reap no advantage from thence. If he should not, before he enters into a capitulation, burn or destroy those magazines, the enemy might insist on their being preserved; but they can think nothing of it, when those precautions are taken before hand.

As soon as the besieged have delivered up a gate of the town to the enemy, the first regiment of the army enters, and mounts guard.

When the day is come that the garrison are to leave the place, the besieging army is drawn up in two files of battalions and squadrons, and the garrison are to pass between them. The hour for their marching out being arrived, the general and the principal officers put themselves at the head of the troops, to see the garrison desfile before them.

The governor puts himself at the head, followed by the principal officers; and he makes the garrison march in the best order possible. The oldest regiments move commonly in the van and the rear, and the others in the centre with their baggage. When there is any cavalry, it is divided in the same manner into three corps, for the van, the centre, and the rear. Small detachments of horse and foot are made to march

along with the baggage, and to take care of its not being rifled.

The artillery granted by the capitulation marches after the first battalion. When the garrison arrive at the place agreed upon, they deliver up the hostages of the besiegers to the escort; and when the latter have rejoined the army, they send back the hostages which the besieged left for the security of the escort, with the waggons, and other things granted by the besieging army for escorting the garrison.

When the garrison are made prisoners of war, they are likewise escorted to the town agreed upon by the terms of the capitulation.

Every thing settled in the capitulation ought to be sacred and inviolable, and should be understood in its genuine and most natural sense: yet as this is not always practised, the governor should take the utmost precaution to have no word inserted that shall be in the least equivocal, or liable to different interpretations. There are a great many examples which prove the necessity of this precaution.

When the garrison of a town capitulate in order to retire to the citadel, there are some particular conditions to be observed, such as follow.

That the citadel shall not be attacked on the side next the town; that the sick and wounded, who cannot be removed, shall stay in their present lodgings; and when they are recovered, they shall be provided with carriages and transports, to retire in safety to the place agreed on in the capitulation. None should be suffered to enter the citadel, but those who may be of use in defending it; the rest, who are called *useless mouths*, by no means ought to be admitted. Mention should be made in the capitulation, that those people shall be conducted to some neighbouring place in the dominions of their sovereign, which should be named. A certain time ought also to be allowed for the whole garrison to enter the citadel; and it should be expressly mentioned, that during this time the besiegers shall construct no works that are necessary for the reduction of the citadel.

A maritime town requires also some particular attention, in regard to the ships that may be in the harbour. It should be stipulated, that they shall quit the harbour the same day as the garrison march out of the town, or when the weather permits to sail to the port agreed upon. They should preserve their artillery, rigging, ammunition, and provisions, &c. If they should be obliged by stress of weather to put into any harbour of the besiegers by the way, it ought to be mentioned in the capitulation, that they shall be received there, and supplied with necessaries for continuing their voyage; they ought also to be provided with passports, and, in a word, to have every kind of security, that they shall not be insulted by the enemy's ships, but suffered without the least obstacle to fleet to the port agreed upon.

W A R

Man of War. See *MAN of War*.

Man-of-War Bird. See *PELICANUS*.

War-Cry was formerly customary in the armies of most nations, when just upon the point of engaging. Sometimes they were only tumultuous shouts, or horrid yells, uttered with an intent to strike terror into

W A R

their adversaries; such as is now used by the Indians in America, called the *war-whoop*.

WARBLES, in farriery. See there § xxxi.

WARD (Dr Seth), an English prelate, chiefly famous for his knowledge in mathematics and astronomy, was born at Buntingford in Hertfordshire, about the

Ward
 Wardrobe.

year 1617. He was admitted of Sidney college, Cambridge, where he applied with great vigour to his studies, particularly to the mathematics, and was chosen fellow of his college. He was involved not a little in the consequences of the civil war, but soon after the Restoration obtained the bishopric of Exeter; in 1667, he was translated to Salisbury, and in 1671 was made chancellor of the order of the garter: he was the first Protestant bishop that enjoyed that honour, and he procured it to be annexed to the see of Salisbury. Bishop Ward was one of those unhappy persons who have the misfortune to survive their senses, which happened in consequence of a fever ill cured; he lived to the revolution without knowing any thing of the matter, and died in 1690. He was the author of several Latin works in mathematics and astronomy, which were thought excellent in their day; but their use has been superseded by later discoveries and the Newtonian philosophy.

WARD (Dr John), was the son of a dissenting minister, and born at London in 1679. He for some years kept a school in Tenter-alley, Moor-fields; but rendered himself so eminent in the study of antiquity, that in 1720 he was chosen professor of rhetoric in Gresham college: in 1723, during the presidency of Sir Isaac Newton, he was elected a fellow of the royal society; and in 1752 one of the vice-presidents, in which office he was continued to his death. He was elected one of the trustees of the British Museum in 1753, and died at Gresham college in 1758. The work for which he is best known, is his *Lives of the Professors of Gresham College*; which is a considerable addition to the history of learning in our country. His *Lectures on Oratory* were published after his death, in 2 vols 8vo.

WARD, is variously used in our old books: a ward in London is a district or division of the city, committed to the special charge of one of the aldermen; and in London there are 26 wards, according to the number of the mayor and aldermen, of which every one has his ward for his proper guard and jurisdiction. A forest is divided into wards; and a prison is called a ward. Lastly, the heir of the king's tenant, that held in *capite*, was termed a ward during his nonage: but this wardship is taken away by the statute 12 Car. II. c. 24.

WARD-Holding, in Scots law. See LAW, N^o clxv. 1. and clxvi. 3.

WARD-Hook, or Wadd-hook, in gunnery, a rod or staff, with an iron end turned serpent-wise, or like a screw, to draw the wadding out of a gun when it is to be unloaded.

WARDEN, or GUARDIAN, one who has the charge or keeping of any person, or thing, by office. Such is the warden of the fleet, the keeper of the fleet prison; who has the charge of the prisoners there, especially such as are committed from the court of chancery for contempt.

WARDHUYS, a port of Norwegian Lapland, 120 miles south-east of the North Cape. E. Long. 28. N. Lat. 71.

WARDMOTE, in London, is a court so called, which is kept in every ward of the city; answering to the *curia comitis* of Rome.

WARDROBE, a closet or little room adjoining

to a bed-chamber, serving to dispose of and keep a person's apparel in; or for a servant to lodge in, to be at hand to wait, &c.

Wardrobe, in a prince's court, is an apartment wherein his robes, wearing apparel, and other necessaries, are preserved under the care and direction of proper officers; as the master of the wardrobe, clerk, &c. of the wardrobe.

WARDSHIP, in chivalry, one of the incidents of tenure by knight-service. See FEODAL System, KNIGHT-Service, and TENURE.

Upon the death of a tenant, if the heir was under the age of 21, being a male, or 14, being a female, the lord was intitled to the wardship of the heir, and was called the *guardian in chivalry*. This wardship consisted in having the custody of the body and lands of such heir, without any account of the profits till the age of 21 in males, and 16 in females. For the law supposed the heir-male unable to perform knight-service till 21; but as for the female, she was supposed capable at 14 to marry, and then her husband might perform the service. The lord therefore had no wardship, if at the death of the ancestor the heir-male was of the full age of 21, or the heir-female of 14: yet if she was then under 14, and the lord once had her in ward, he might keep her so till 16, by virtue of the statute of Westm. 1. 3 Edw. I. c. 22. the two additional years being given by the legislature for no other reason but merely to benefit the lord.

This wardship, so far as it related to land, though it was not nor could be part of the law of feuds, so long as they were arbitrary, temporary, or for life only; yet when they became hereditary, and did consequently often descend upon infants, who by reason of their age could neither perform nor stipulate for the services of the feud, does not seem upon feudal principles to have been unreasonable. For the wardship of the land, or custody of the feud, was retained by the lord, that he might out of the profits thereof provide a fit person to supply the infant's services till he should be of age to perform them himself. And if we consider a feud in its original import, as a stipend, fee, or reward for actual service, it could not be thought hard that the lord should withhold the stipend so long as the service was suspended. Though undoubtedly to our English ancestors, where such stipendiary donation was a mere supposition or signment, it carried abundance of hardship; and accordingly it was relieved by the charter of Henry I. before-mentioned, which took this custody from the lord; and ordained that the custody, both of the land and the children, should belong to the widow or next of kin. But this noble immunity did not continue many years.

The wardship of the body was a consequence of the wardship of the land; for he who enjoyed the infant's estate was the properest person to educate and maintain him in his infancy: and also in a political view, the lord was most concerned to give his tenant a suitable education, in order to qualify him the better to perform those services which in his maturity he was bound to render.

When the male heir arrived to the age of 21, or the heir-female to that of 16, they might sue out their *livery* or *ousterlemain*; that is, the delivery of their lands out of their guardian's hands. For this they were obliged

Wardship.

Wardship, ligned to pay a fine, namely, half a year's profits of the land; though this seems expressly contrary to *magna carta*. However, in consideration of their lands having been so long in ward, they were excused all reliefs, and the king's tenants also all primer feins. In order to ascertain the profits that arose to the crown by these fruits of tenure, and to grant the heir his livery, the itinerant justices, or justices in eyre, had it formerly in charge to make inquisition concerning them by a jury of the county, commonly called an *inquisitio post mortem*; which was instituted to inquire (at the death of any man of fortune) the value of his estate, the tenure by which it was holden, and who, and of what age, his heir was; thereby to ascertain the relief and value of the primer fein, or the wardship and livery accruing to the king thereupon. A manner of proceeding that came in process of time to be greatly abused, and at length an intolerable grievance; it being one of the principal accusations against Empson and Dudley, the wicked engines of Henry VII. that by colour of false inquisitions they compelled many persons to sue out livery from the crown, who by no means were tenants thereunto. And afterwards a court of wards and liveries was erected, for conducting the same inquiries in a more solemn and legal manner.

When the heir thus came of full age, provided he held a knight's fee, he was to receive the order of knighthood, and was compellable to take it upon him, or else pay a fine to the king. For in those heroic times, no person was qualified for deeds of arms and chivalry who had not received this order, which was conferred with much preparation and solemnity. We may plainly discover the footsteps of a similar custom in what Tacitus relates of the Germans, who, in order to qualify their young men to bear arms, presented them in a full assembly with a shield and lance; which ceremony, as was formerly hinted, is supposed to have been the original of the feudal knighthood. This prerogative, of compelling the vassals to be knighted, or to pay a fine, was expressly recognized in parliament, by the statute *de militibus*, 1 Edw. II.; was exerted as an expedient for raising money by many of our best princes, particularly by Edw. VI. and queen Elizabeth; but this was the occasion of heavy murmurs when exerted by Charles I.: among whose many misfortunes it was, that neither himself nor his people seemed able to distinguish between the arbitrary stretch and the legal exertion of prerogative. However, among the other concessions made by that unhappy prince before the fatal recourse to arms, he agreed to divest himself of this undoubted flower of the crown; and it was accordingly abolished by stat. 16 Car. I. c. 20.

WARE, a town of Hertfordshire, with a market on Tuesdays, and a fair on the last Tuesday in April, and Tuesday before St. Matthew's day (Sept. 21.) for horses and other cattle. It is a large, well frequented, and well inhabited thoroughfare town, seated on the river Lea, 21 miles north of London. It carries on a great trade in malt and corn, which they are continually sending in large quantities to London. E. Long. o. 3. N. Lat. 51. 50.

WARE (Sir James), in Latin *Wareus*, a celebrated antiquarian and historian, was the son of Sir James Ware, and was born at Dublin on the 26th of November 1604. He was educated at Trinity college in

that city, where he made an uncommon proficiency. He afterwards received the honour of knighthood, and upon the death of his father enjoyed his post of auditor-general of Ireland. In 1639 he was made one of the privy-council of that kingdom; and when the rebellion broke out there, suffered much in his estate. In 1644 the marquis of Ormond, who enjoyed the post of lord-lieutenant, sent him with two lords to Charles I. who was then in Oxford, about some important affairs, which were concluded to their satisfaction; but in their return they were taken by a parliament ship, and committed prisoners to the Tower of London, where he was detained 11 months. He was afterwards forced to retire to France, where he staid a year and a half. Then coming to England, he settled in London, where he composed several of his works. Upon the restoration he returned to Ireland, and was restored to his places of auditor-general and privy-counsellor. He wrote in Latin, Annals of the reigns of Henry VI. Henry VIII. Edward VI. and Mary; a Treatise on the Writers of Ireland; and many other works. He died at Dublin in 1666.

WARN, in law, is to summon a person to appear in a court of justice.

WARNING of TENANTS, in Scots law. See LAW, N° clxvii. 16.

WARP, in the manufactures, a name for the threads, whether of silk, wool, linen, hemp, &c. that are extended lengthwise on the weaver's loom; and across which the workman, by means of his shuttle, passes the threads of the woof, to form a cloth, ribband, fustian, or the like.

WARP, a small rope employed occasionally to remove a ship from one place to another, in a port, road, or river. And hence,

To WARP, is to change the situation of a ship, by pulling her from one part of a harbour, &c. to some other, by means of warps, which are attached to buoys; to anchors sunk in the bottom; or to certain stations upon the shore, as posts, rings, trees, &c. The ship is accordingly drawn forwards to those stations, either by pulling on the warps by hand, or by the application of some purchase, as a tackle, windlass, or capstern, upon her deck.

When this operation is performed by the ship's lesser anchors, these machines, together with their warps, are carried out in the boats alternately towards the place where the ship is endeavouring to arrive: so that when she is drawn up close to one anchor, the other is carried out to a competent distance before her, and being sunk, serves to fix the other warp by which she is farther advanced.

Warping is generally used when the sails are unbent, or when they cannot be successfully employed, which may either arise from the unfavourable state of the wind, the opposition of the tide, or the narrow limits of the channel.

WARRANTICE, in Scots law. See LAW, N° clxiv. 11.

WARRANT, an act, instrument, or obligation, whereby a person authorizes another to do something which he otherwise had not a right to do.

A warrant may be granted in extraordinary cases by the privy council, or secretaries of state; but ordinarily by justices of the peace. This they may do in any cases

cafes where they have a jurisdiction over the offence, in order to compel the person accused to appear before them: for it would be absurd to give them power to examine an offender, unless they had also a power to compel him to attend, and submit to such examination. And this extends undoubtedly to all treasons, felonies, and breaches of the peace; and also to all such offences as they have power to punish by statute. Sir Edward Coke indeed hath laid it down, that a justice of the peace cannot issue a warrant to apprehend a felon upon bare suspicion; no, not even till an indictment be actually found: and the contrary practice is by others held to be grounded rather upon conviction than the express rule of law; though now by long custom established. A doctrine which would in most cases give a loose to felons to escape without punishment; and therefore Sir Matthew Hale hath combated it with invincible authority and strength of reason: Maintaining, 1. That a justice of peace hath power to issue a warrant to apprehend a person accused of felony, tho' not yet indicted; and, 2. That he may also issue a warrant to apprehend a person suspected of felony, though the original suspicion be not in himself, but in the party that prays his warrant; because he is a competent judge of the probability offered to him of such suspicion. But in both cases it is fitting to examine upon oath the party requiring a warrant, as well to ascertain that there is a felony or other crime actually committed, without which no warrant should be granted; as also to prove the cause and probability of suspecting the party against whom the warrant is prayed. This warrant ought to be under the hand and seal of the justice, should set forth the time and place of making, and the cause for which it is made, and should be directed to the constable, or other peace-officer, (or it may be to any private person by name), requiring him to bring the party either generally before any justice of the peace for the county, or only before the justice who granted it: the warrant in the latter case being called a *special warrant*. A general warrant to apprehend all persons suspected, without naming or particularly describing any person in special, is illegal and void for its uncertainty; for it is the duty of the magistrate, and ought not to be left to the officer, to judge of the ground of suspicion. And a warrant to apprehend all persons, guilty of a crime therein specified, is no legal warrant: for the point upon which its authority rests, is a fact to be decided on a subsequent trial; namely, whether the person apprehended thereupon be really guilty or not. It is therefore in fact no warrant at all; for it will not justify the officer who acts under it: whereas a warrant, properly penned (even though the magistrate who issues it should exceed his jurisdiction), will, by statute 24 Geo. II. c. 44. at all events indemnify the officer who executes the same ministerially. And when a warrant is received by the officer, he is bound to execute it, so far as the jurisdiction of the magistrate and himself extends. A warrant from the chief, or other justice of the court of king's-bench, extends all over the kingdom; and is test'd, or dated, England; not Oxfordshire, Berks, or other particular county. But the warrant of a justice of the peace in one county, as Yorkshire, must be backed, that is, signed by a justice of the peace in another, as Middlesex, before it can be executed there.

Formerly, regularly speaking, there ought to have been a fresh warrant in every fresh county; but the practice of backing warrants had long prevailed without law, and was at last authorized by stat. 23 Geo. II. c. 26. and 24 Geo. II. c. 55. And now, by statute 13 Geo. III. c. 31. any warrant for apprehending an English offender, who may have escaped into Scotland, and *vice versa*, may be indorsed and executed by the local magistrates, and the offender conveyed back to that part of the united kingdoms in which such offence was committed.

WARREN (Sir Peter), an admiral, distinguished by his virtue, learning, and undaunted courage, was descended from an ancient family in Ireland, and received a suitable education to qualify him for a command in the royal navy, in which he served for several years with great reputation; but the transaction which placed his great abilities in their full light, was the taking of Louisburg in the year 1745, when he was appointed commodore of the British squadron sent on that service. He joined the fleet of transports from Boston in Casco-bay on the 25th of April, having under his command the *Superb* of 60, and the *Launceston* and *Eltham* of 40 guns; he was afterwards joined by several other men of war sent from England, and took possession of Louisburg on the 17th of June. The French, exasperated at this loss, were constantly on the watch to retake it; and in 1747 fitted out a large fleet for that purpose, and at the same time another squadron to prosecute their success in the East-Indies. These squadrons failed at the same time; but the views of the French were rendered abortive by the gallant admiral Anson and Mr Warren, who had been created rear-admiral, who with a large fleet of ships fell in with the French, defeated the whole fleet, and took the greatest part of the men of war. This was the last service Sir Peter rendered to his country as a commander in the British fleet; for a peace being concluded in the succeeding year, the fleet was laid up in the several harbours.

He was now chosen one of the representatives in parliament for Westminster; and in the midst of his popularity he paid a visit to Ireland, his native country, where he died of an inflammatory fever in 1752, sincerely lamented by all ranks of people; and an elegant monument of white marble was erected to his memory in Westminster-abbey.

WARREN, is a franchise or place privileged by prescription or grant from the king, for the keeping of beasts and fowls of the warren; which are hares and coney, partridges, pheasants, and some add quails, woodcocks, and water-fowl, &c. These being *feræ nature*, every one had a natural right to kill as he could: but upon the introduction of the forest laws at the Norman conquest, these animals being looked upon as royal game, and the sole property of our savage monarchs, this franchise of free-warren was invented to protect them, by giving the grantee a sole and exclusive power of killing such game, so far as his warren extended, on condition of his preventing other persons. A man therefore that has the franchise of warren, is in reality no more than a royal game-keeper: but no man, not even a lord of a manor, could by common law justify sporting on another's soil, or even on his own, unless

he had the liberty of free-warren. This franchise is almost fallen into disrepute since the new statutes for preserving the game; the name being now chiefly preserved in grounds that are set apart for breeding hares and rabbits. There are many instances of keen sportsmen in ancient times, who have sold their estates, and reserved the free-warren, or right of killing game, to themselves; by which means it comes to pass that a man and his heirs have sometimes free-warren over another's ground.

A warren may lie open; and there is no necessity of inclosing it as there is of a park. If any person offend in a free warren, he is punishable by the common law, and by stat. 21 Edw. III. And if any one enter wrongfully into any warren, and chase, take, or kill any coney without the consent of the owner, he shall forfeit treble damages, and suffer three months imprisonment, &c. by 22 and 23 Car. II. c. 25. When coney are on the soil of the party, he hath a property in them by reason of the possession, and action lies for killing them; but if they run out of the warren and eat up a neighbour's corn, the owner of the land may kill them, and no action will lie.

WARSAW, the capital of Warovia in Poland, and indeed of the whole kingdom, stands on the Vistula, almost in the centre of the kingdom, and in N. Lat. 52. 14. and E. Long. 21. ; 154 miles south-east of Dantzic, 133 north of Cracow, and 300 north of Vienna. Here the king usually keeps his court in a large square palace, standing amidst delicate gardens and groves; and at this place are held the general diets, where there is such a concourse of people, that great numbers of them are obliged to live in tents. The city is large and populous, contains a great many churches, palaces, and convents, both within and without the walls, and is pretty well fortified. Here is also a stately castle, an arsenal, and a curious wooden bridge over the river. Count Zaluski's library, said to contain 200,000 volumes, was opened in 1746. The ordinary diets are held at the royal palace; but during the interregnum, in a field not far from the city, near the village of Wola. Goods are brought to the city by the Vistula and other rivers, and sent from thence to Dantzic. Baron Polnitz, who spent some time in this city, says, he observed the same politeness here as at Paris; that the ladies are amiable, witty, and sprightly, and passionately fond of music and plays. Near this city are two royal palaces, viz. Vialdow, pleasantly situated on the Vistula, and Villanow, where, in 1732, Augustus II. reviewed his troops, and made them go through all the different military exercises.

WART, in surgery, a little round hard excrecence, being first a small and almost imperceptible induration of the skin, which if observed in time may be easily eradicated. If suffered to remain, it penetrates deeper into the cellular membrane, and sends forth roots, frequently becoming cancerous if irritated by the imprudent use of caustics.

WARWICK, the capital of Warwickshire in England, and from which this county derives its name. It is very ancient, and supposed by Camden to be the place called by the Romans *Præsidium*, where the Dalmatian horse were posted. It stands on a rock of free-stone, of which all the public edifices in the town are built. At the Norman invasion it was a

considerable place; and had many burgessees, of whom 12 were obliged by their tenure to accompany the king in his wars. The castle was anciently very strong, both by nature and art, and is now a most noble and delightful dwelling; the rock on which it stands being 40 feet above the river, but on the north side level with the town. In September 1694, the city suffered much by a fire, occasioned by a spark blown from a stick, as it was carrying coals a lane; but by an act of parliament for rebuilding it, and the liberal contributions of the nation, it hath risen again out of its ashes more magnificent than it was before. It is supplied with water brought in pipes from springs half a mile from the town, besides what it derives from the wells within it made in the rock; and it is easily kept clean, by being situated upon a declivity. Four streets, from the four cardinal points of the compass, meet in the centre of the town. The country all around is very beautiful; of which, from a terrace in the castle, now the seat of earl Brook and Warwick, there is a very noble prospect. The principal public buildings are St Mary's, a very stately edifice, an hospital, a town-house of free-stone, three charity schools, and a noble bridge over the Avon. It has had several charters; but is governed at present by a mayor, 12 brethren, 24 burgessees, &c. It is a very handsome populous town, and gives title of earl to the family of the Grevilles.

WASH, among distillers, the fermentable liquor used by the malt distillers. See BREWERY.

WASHING, in painting, is when a design, drawn with a pen or crayon, has some one colour laid over it with a pencil, as Indian ink, bistre, or the like, to make it appear the more natural, by adding the shadow of prominences, aperture, &c. and by imitating the particular matters whereof the thing is supposed to consist.

Thus they wash with a pale red, to imitate brick and tile; with a pale Indian blue, to imitate water and slate; with green, for trees and meadows; with saffron or French berries, for gold or brass; and with several colours for marbles.

WASHING of Ores, the purifying an ore of any metal, by means of water, from earths and stones, which would otherwise render it difficult of fusion.

WASP, in zoology. See VESPA.

WATCH, in the art of war, a number of men posted at any passage, or a company of the guards who go on the patrol.

WATCH, in the navy, the space of time wherein one division of a ship's crew remains upon deck, to perform the necessary services, whilst the rest are relieved from duty, either when the vessel is under sail or at anchor.

The length of the sea-watch is not equal in the shipping of different nations. It is always kept four hours by our British seamen, if we except the dog-watch between four and eight in the evening, that contains two reliefs, each of which are only two hours on deck. The intent of this is to change the period of the night-watch every 24 hours; so that the party watching from 8 till 12 in one night, shall watch from midnight till four in the morning on the succeeding one. In France the duration of the watch is extremely different, being in some places six hours, and in others

others seven or eight : and in Turkey and Barbary it is usually five or six hours.

A ship's company is usually classed into two parties ; one of which is called the starboard and the other the larboard watch. It is, however, occasionally separated into three divisions, as in a road or in particular voyages.

In a ship of war the watch is generally commanded by a lieutenant, and in merchant-ships by one of the mates : so that if there are four mates in the latter, there are two in each watch ; the first and third being in the larboard, and the second and fourth in the starboard watch : but in the navy, the officers who command the watch usually divide themselves into three parties, in order to lighten their duty.

WATCH, is also used for a small portable movement, or machine, for the measuring of time ; having its motion regulated by a spiral spring.

Watches, strictly taken, are all such movements as show the parts of time ; as clocks are such as publish it, by striking on a bell, &c. But commonly the name *watch* is appropriated to such as are carried in the pocket ; and *clock* to the large movements, whether they strike the hour or not. See *Clock*.

The invention of spring or pocket-watches, belongs to the present age. It is true, we find mention made of a watch presented to Charles V. in the history of that prince : but this, in all probability, was no more than a kind of clock to be set on a table, some resemblance whereof we have still remaining in the ancient pieces made before the year 1670. In effect, it is between Dr Hooke and M. Huygens that the glory of this excellent invention lies : but to which of them it properly belongs, is greatly disputed ; the English ascribing it to the former, and the French, Dutch, &c. to the latter. Mr Derham, in his *Artificial Clockmaker*, says roundly, that Dr Hooke was the inventor ; and adds, that he contrived various ways of regulation. One way was with a loadstone. Another with a tender straight spring, one end whereof played backwards and forwards with the balance ; so that the balance was to the spring as the bob to a pendulum, and the spring as the rod thereof. A third method was with two balances, of which there were divers sorts ; some having a spiral spring to the balance for a regulator, and others without. But the way that prevailed, and which continues in mode, was with one balance, and one spring running round the upper part of the verge thereof : Though this has a disadvantage, which those with two springs, &c. were free from ; in that a sudden jerk, or confused shake, will alter its vibrations, and put it in an unusual hurry.

The time of these inventions was about the year 1658 ; as appears, among other evidences, from an inscription on one of the double balance watches presented to king Charles II. viz. Rob. Hooke Inven. 1658. T. Tompion fecit, 1675. The invention presently got into reputation, both at home and abroad ; and two of them were sent for by the dauphin of France. Soon after this, M. Huygens's watch with a spiral spring got abroad, and made a great noise in England, as if the longitude could be found by it. It is certain, however, that his invention was later than the year 1673, when his book de *Horol. Oscillat.* was published ; wherein he has not one word of this, though

VOL. X.

he has of several other contrivances in the same way.

One of these the lord Brouncker sent out of France, where M. Huygens had got a patent for them. This watch agreed with Dr Hooke's, in the application of the spring to the balance ; only M. Huygens's had a longer spiral spring, and the pulses and beats were much slower. The balance, instead of turning quite round, as Dr Hooke's, turns several rounds every vibration.

Mr Derham suggests, that he has reason to doubt M. Huygens's fancy first was set to work by some intelligence he might have of Dr Hooke's invention from Mr Oldenburg, or some other of his correspondents in England ; though Mr Oldenburg vindicates himself against that charge, in *Philosophical Transactions*, N^o 118 and 129. Huygens invented divers other kinds of watches, some of them without any spring or chain at all ; which he called, particularly, *pendulum watches*.

As it was in England that watches had their first rise ; so it is there too they have arrived at their greatest perfection. Witness that exceeding value put on an English watch in all foreign countries, and that vast demand made for them.

M. Savary, in his *Diction. de commerce*, pretends to match the French watchmakers against the English. He asserts, " That if the English be in any condition to dispute it with them, they owe it entirely to the great number of French workmen who took shelter here upon the revocation of the edict of Nantz." He adds, " That three fourths of the watches made in England are the work of Frenchmen."—From what authorities he says this we know not : but it need not be told Englishmen that it is false ; there not being one French name, that we know of, among all our famed watchmakers ; nor, in the body of watchmakers, is there one eighth part French.

It is certain the French people prefer our watches vastly to their own ; inasmuch, that to have them with the more ease, a number of English workmen were invited over in 1719, and established with great countenance at Versailles, under the direction of the famous Mr Law. But the establishment, though every thing promised well for it, and the French watch and clock makers seemed undone by it, fell to the ground in less than a year's time. M. Savary imputes its fall entirely to that strong prejudice of the French people in behalf of the English workmen, and to the opinion that the watches did not come from England. But the truth is, the workmen sent over being most of them men of loose characters, grew dissolute, quarrelled with the priests, insulted the magistrates, and were dismissed of necessity.

Striking WATCHES are such, as besides the proper watch part for measuring of time, have a clock-part for striking the hours, &c.

Repeating WATCHES, are such as by pulling a string, &c. repeat the hour, quarter, or minute, at any time of the day or night.—This repetition was the invention of Mr Barlow, and first put in practice by him in larger movements or clocks about the year 1676. The contrivance immediately set the other artists to work, who soon contrived divers ways of effecting the same. But its application to pocket-watches was not known before king James the Second's reign ; when

44 X

the

Watch.

the ingenious inventor above-mentioned, having directed Mr Thompson to make a repeating watch, was soliciting a patent for the same. The talk of a patent engaged Mr Quare to resume the thoughts of a like contrivance, which he had had in view some years before: he now effected it; and being pressed to endeavour to prevent Mr Barlow's patent, a watch of each kind was produced before the king and council; upon trial of which, the preference was given to Mr Quare's. The difference between them was, that Barlow's was made to repeat by pushing in two pieces on each side the watch-box; one of which repeated the hour, and the other the quarter: whereas Quare's was made to repeat by a pin that stuck out near the pendant, which being thrust in (as now it is done by thrusting in the pendant itself), repeated both the hour and quarter with the same thrust.

Plate
LXXX.
(Vol. III.)

Of the Mechanism of a WATCH. Watches, as well as clocks, are composed of wheels and pinions, and a regulator to direct the quickness or slowness of the wheels, and of a spring which communicates motion to the whole machine. But the regulator and spring of a watch are vastly inferior to the weight and pendulum of a clock, neither of which can be employed in watches. In place of a pendulum, therefore, we are obliged to use a balance (fig. 4.) to regulate the motion of a watch; and of a spring (fig. 6.) which serves in place of a weight, to give motion to the wheels and balance.

The wheels of a watch, like those of a clock, are placed in a frame formed of two plates and four pillars. Fig. 3. represents the inside of a watch, after the plate (fig. 5.) is taken off. A is the barrel which contains the spring (fig. 6.) the chain is rolled about the barrel, with one end of it fixed to the barrel A, and the other to the fusee B.

When a watch is wound up, the chain which was upon the barrel winds about the fusee, and by this means the spring is stretched; for the interior end of the spring is fixed by a hook to the immovable axis, about which the barrel revolves; the exterior end of the spring is fixed to the inside of the barrel, which turns upon an axis. It is therefore easy to perceive how the spring extends itself, and how its elasticity forces the barrel to turn round, and consequently obliges the chain which is upon the fusee to unfold and turn the fusee; the motion of the fusee is communicated to the wheel CC; then, by means of the teeth, to the pinion *c*, which carries the wheel D; then to the pinion *d*, which carries the wheel E; then to the pinion *e*, which carries the wheel F; then to the pinion *f*, upon which is the balance-wheel G, whose pivot runs in the pieces A called the *potance*, and B called a *follower*, which are fixed on the plate fig. 5. This plate, of which only a part is represented, is applied to that of fig. 3. in such a manner, that the pivots of the wheels enter into holes made in the plate fig. 3. Thus the impressed force of the spring is communicated to the wheels: and the pinion *f* being then connected to the wheel F, obliges it to turn (fig. 7.) This wheel acts upon the palettes of the verge 1. 2. (fig. 4.) the axis of which carries the balance H, (fig. 4.) The pivot I, in the end of the verge, enters into the hole *c* in the potance A (fig. 5.) In this figure the palettes are represented; but the balance

is on the other side of the plate, as may be seen in fig. 11. The pivot 3 of the balance enters into a hole of the cock BC, (fig. 10.) a perspective view of which is represented in (fig. 12.) Thus the balance turns between the cock and the potance *c*, (fig. 5.) as in a kind of cage. The action of the balance-wheel upon the palettes 1, 2, (fig. 4.) is the same with what we have described with regard to the same wheel in the clock; *i. e.* in a watch the balance-wheel obliges the balance to vibrate backwards and forwards like a pendulum. At each vibration of the balance a palette allows a tooth of the balance-wheel to escape; so that the quickness of the motion of the wheels is entirely determined by the quickness of the vibrations of the balance, and these vibrations of the balance and motion of the wheels are produced by the action of the spring.

But the quickness or slowness of the vibrations of the balance depend not solely upon the action of the great spring, but chiefly upon the action of the spring *a, b, c*, called the *spiral spring*, (fig. 14.) situated under the balance H, and represented in perspective (fig. 11.) The exterior end of the spiral is fixed to the pin *a*, (fig. 14.) This pin is applied near the plate in *a*, (fig. 11.); the interior end of the spiral is fixed by a peg to the centre of the balance. Hence if the balance is turned upon itself, the plates remaining immovable, the spring will extend itself, and make the balance perform one revolution. Now, after the spiral is thus extended, if the balance be left to itself, the elasticity of the spiral will bring back the balance, and in this manner the alternate vibrations of the balance are produced.

In fig. 7. all the wheels above described are represented in such a manner, that you may easily perceive at first sight how the motion is communicated from the barrel to the balance.

In fig. 8. are represented the wheels under the dial-plate by which the hands are moved. The pinion *a* is adjusted to the force of the prolonged pivot of the wheel D, (fig. 7.) and is called a *canon pinion*. This wheel revolves in an hour. The end of the axis of the pinion *a*, upon which the minute-hand is fixed, is square; the pinion (fig. 8.) is indented into the wheel *b*, which is carried by the pinion *a*. Fig. 9. is a wheel fixed upon a barrel, into the cavity of which the pinion *a* enters, and upon which it turns freely. This wheel *d* revolves in 12 hours, and carries along with it the hour-hand.

WATCHING, in medicine, is when, through too great a determination of blood to the head, or emptiness of the vessels, and an exhausted state of the body, the patient cannot sleep. In fevers it is a dangerous symptom, and if long continued ends in a delirium.

WATER, in physiology, a clear insipid and colourless fluid, coagulable into a transparent solid substance at 32° of Fahrenheit's thermometer, and volatile in every degree of heat above that. Many different kinds of waters are commonly spoken of, such as Chalybeate waters, sulphureous, saline, putrid waters, &c. but all these differ from one another only in having various substances mixed with them, from which when perfectly freed, the water is always the same; so that it has not improperly been reckoned one of the four elements.

Watch
||
Water.

The general and most effectual method of freeing water from any heterogeneous substance is distillation. Thus it may be perfectly purified from almost every saline substance whatever; and thus sea-water may be rendered perfectly fresh and wholesome. It must be observed, however, that all distilled water acquires an empyreumatic smell and taste by this operation; so that it makes but disagreeable drink until it has stood for some time. Another disadvantage which attends water when newly distilled, is its want of fixed air; which, however, it soon recovers by exposure to the air for some time. If water is actually putrid, it cannot be made fit for use by simple distillation. In this case a quantity of lime is necessary, which extracts a volatile alkali, but destroys the putrid substance. After the water is once distilled in this manner, it may be more fully purified by adding some vitriolic or other acid to neutralise the alkali, and redistilling it with this addition. The substance from which it is most difficult to free water is any volatile oil. This rises in distillation, and will also pass through every kind of strainer. The only cure in this case therefore is to expose the fluid for a considerable time to the air, when the oil will fly off or become effete and fixed, so that it cannot rise in distillation; after which the water may easily be purified.

Whether or not it is possible to convert water into earth, is a question which has much engaged the attention of philosophers. Mr Boyle relates, that a friend of his, by distilling a quantity of water an hundred times, found at length, that he had got six-tenths of the first quantity in earth: whence he concludes, that the whole water, by further prosecuting the operation, might be converted into earth. Others have made experiments to the same purpose, and seemingly with the same success; but the deception is now found out. Water has the power of corroding the hardest bodies, even glass itself, by long digestion, especially when assisted by heat; and hence those who have made the experiments just mentioned have been themselves deceived, by supposing the earth which really came from the containing vessel to come from the water.

It is surprising to consider the plenteous stock of water which even dry bodies afford. Hartshorn kept forty years, and turned as hard and dry as any metal, so that if struck against a flint it will yield sparks of fire; yet being put into a vessel, and distilled, will afford one-eighth part of its quantity of water. Bones dead and dried 25 years, and thus become almost as hard as iron; yet, by distillation, have afforded half their weight of water. And the hardest stones, ground and distilled, do always discover a portion thereof.

From considerations of this kind, Thales, and some other philosophers, have been led to hold, that all things were made of water; which opinion, probably, had its rise from the writings of Moses, where he speaks of the spirit of God moving upon the face of the waters: But Mr Boyle does not conceive the water here mentioned by Moses as the universal matter, to be our elementary water: we need only suppose it an agitated congeries of a great variety of seminal principles, and of other corpuscles fit to be subdued and fashioned by them; and it may yet be a body fluid like water, in case the corpuscles it was made up of were by their

Creator made small enough, and put into such an actual motion as might make them roll and glide easily over one another. However, Basil Valentine, Paracelsus, Van Helmont, Sendivogius, and others, have maintained the same principle, viz. that water is the elemental matter or flamen of all things, and suffices alone for the production of all the visible creation. Thus Sir Isaac Newton, "All birds, beasts, and fishes, insects, trees, and vegetables, with their several parts, do grow out of water, and watery tinctures, and salts; and, by putrefaction, return again to watery substances."

Helmont endeavours to prove this doctrine from an experiment; wherein, burning a quantity of earth till all the oil was consumed, and then mixing it up with water to draw out all the salt; and putting this earth, thus prepared, into an earthen pot, which nothing but rain-water could enter; yet a willow, planted therein, grew up to a considerable height and bulk, without any sensible diminution of the earth: whence he concluded, that the water was the only nutriment of the vegetable kind, as vegetables are of the animal. The same thing is inferred by Mr Boyle, from a parallel experiment: and the whole is countenanced by Sir Isaac Newton, who observes, that water, standing a few days in the open air, yields a tincture, which, like that of malt, by standing longer, yields a sediment, and a spirit; but before putrefaction, is fit nourishment for animals and vegetables.

But Dr Woodward endeavours to shew the whole a mistake: water containing extraneous corpuscles, some of these, he shows, are the proper matter of nutrition; the water being still found to afford so much the less nourishment the more it is purified by distillation. Thus a plant in distilled water will not grow so fast as in water not distilled; and if the water be distilled three or four times over, the plant will scarce grow at all, or receive any nourishment from it. So that water, as such, does not seem the proper nutriment of vegetables, but only the vehicle thereof, which contains the nutritious particles, and carries them along with it through all the parts of the plant. See AGRICULTURE, sect. i. ii.

No standard for the weight and purity of water.—Water scarce ever continues two moments exactly of the same weight, by reason of the air and fire contained therein. Thus, a piece of pure limpid ice, laid in a nice balance, never continues in equilibrio. In effect, the expansion of water in boiling, shows what effect the different degree of fire has, on the gravity of water. This makes it difficult to fix the specific gravity of water, in order to settle its degree of purity; but this we may say in the general, that the purest water we can procure, is that which is 880 times as heavy as air. However, neither have we any tolerable standard in air: for, water being so much heavier than air, the more water is contained in the air, the heavier of course must it be; as, in effect, the principal part of the weight of the atmosphere seems to arise from the water.

Property and effects of water.—Water is found the most penetrative of all bodies, after fire, and the most difficult to confine; so that a vessel through which water cannot pass may retain any thing. Nor is it any objection, that syrups and oils will sometimes pass

through bodies which will hold water; this not being owing to the greater subtlety and penetration of their particles, but to the refin wherewith the wood of such vessels abounds, to which oils and fyrups are as menstrooms; so that, dissolving the refin, they make their way through the spaces left thereby: whereas water, not acting on refin, is retained.

And yet water gradually makes its way even through all woods, and is only retainable in glass and metals; nay, it was found by experiment at Florence, that when shut up in a spherical vessel of gold, and then violently pressed with a huge force, it made its way through the pores even of the gold: so that the moist solid body in nature is permeable to water.

Water has been supposed more fluid than air; a body being reputed more fluid than another, when its parts will find way through smaller pores: now air, it is known, will not pass through leather, as is evident in the case of an exhausted receiver covered therewith; whereas water passes with ease. Again, air may be retained in a bladder, but water oozes through. In effect, it is found, that water will pass through pores ten times smaller than air will. M. Homborg, however accounts for this passage of water through the narrow pores of animal substances which will not admit the air, on another principle, viz. its moistening and dissolving the glutinous matter of the fine fibres of the membranes, and rendering them more pliable and distensible; which the air, for want of a wetting property, cannot do. As a proof of this doctrine, he filled a bladder, and compressed it with a stone, and found no air to come out; but placing the bladder thus compressed in water, the air easily escaped.

This property of water, joined with its smoothness and lubricity, fits it to serve as a vehicle for the commodious and easy conveyance of the nutritious matter of all bodies: being so fluid, and passing and repassing so readily, it never stops up the pores, but leaves room for the following water to bring on a new supply of nutritious matter. And yet the same water, as little cohesive as it is, and as easily separated from moist bodies, according to some is the principle of union in a great number of bodies, and binds them together into the most solid masses. Water, we see, mixed up with earth or ashes, gives them the utmost firmness and fixity. The ashes, *e. gr.* of an animal, incorporated with pure water into a paste, and baked with a vehement fire, grow into a coppel; which is a body remarkable for this, that it will bear the utmost effort of a refiner's furnace. It is, in effect, upon the glutinous nature of water alone that our houses stand: for take but this out of wood, and it becomes ashes; or out of tiles, and they become dust. Thus, a little clay dried in the sun, becomes a powder, which, mixed with water, sticks together again, and may be fashioned at pleasure; and this dried again by a gentle fire, or in the sun, and then baked in a potter's oven by an intense fire, becomes little other than a stone. It cannot however be proved that the small quantity of water supposed to remain in bricks, &c. is the cause of their cohesion. It seems more probable that an incipient vitrification is the reason why bricks and earthen ware of all kinds stick together. Some of these, porcelain and stone ware in particular, are evidently vitrified.

For a long time water was supposed to be incompressible, or incapable of being, by any force whatever, reduced into a less compass. This was thought to be demonstrated by the famous experiment above-mentioned, made by order of the great duke of Tuscany. The water being incapable of condensation, rather than yield, transuded through the pores of the metal, so that the ball was found wet all over the outside; till at length making a cleft in the gold, it sprung out with great vehemence. From this last circumstance, indeed, some have weakly concluded it was elastic. For the impetus wherewith the water darted forth, was more probably owing to the elasticity of the gold, which communicated that impression to the water.—Of late, however, the contrary opinion has been adopted; and Mr Canton has made some experiments to show, that water not only may be, but actually is, compressed, by the weight of the atmosphere. These we shall relate in his own words. "Having procured a small glass-tube of about two feet in length, with a ball at one end of it of an inch and a quarter in diameter, I filled the ball and part of the tube with mercury; and keeping it with a Fahrenheit's thermometer in water which was frequently stirred, it was brought exactly to the heat of 50°; and the place where the mercury stood in the tube, which was about 6½ inches above the ball, was carefully marked. I then raised the mercury by heat to the top of the tube, and sealed the tube hermetically; and when the mercury was brought to the same degree of heat as before, it stood in the tube $\frac{1}{10}$ of an inch higher than the mark.

"The same ball, and part of the tube, being filled with water exhausted of air instead of the mercury, and the place where the water stood in the tube when it came to rest in the heat of 50° being marked, which being sealed six inches above the ball, the water was then raised by heat till it filled the tube; which being sealed again, and the water brought to the heat of 50° as before, it stood in the tube $\frac{1}{10}$ of an inch above the mark.

"Now the weight of the atmosphere (or about 73 pounds averdupois) pressing on the outside of the ball and not on the inside, will squeeze it into less compass. And by this compression of the ball the mercury and water will be equally raised in the tube: but the water is found, by the experiments above related, to rise $\frac{1}{10}$ of an inch more than the mercury, by removing the weight of the atmosphere.

"In order to determine how much water is compressed by this or a greater weight, I took a glass ball of about an inch and $\frac{1}{10}$ in diameter, which was joined to a cylindrical tube of four inches and $\frac{1}{10}$ in length, and diameter about $\frac{1}{10}$ of an inch; and by weighing the quantity of mercury that exactly filled the whole length of the tube, I found that the mercury in $\frac{3}{10}$ of an inch of the tube, was the 100,000th part of that contained in the ball; and with the edge of a file I divided the tube accordingly.

"This being done, I filled the ball and part of the tube with water exhausted of air; and left the tube open, that the ball, whether in rarefied or condensed air, might always be equally pressed within and without, and therefore not altered in its dimensions. Now by placing this ball and tube under the receiver of an air-pump, I could see the degree of expansion of the

water

Water.

water answering to any degree of rarefaction of the air; and by putting it into a glass receiver of a condensing engine, I could see the degrees of compression of the water answering to any degree of condensation of the air. But great care must be taken in making these experiments, that the heat of the glass ball be not altered, either by the coming on of moisture, or its going off by evaporation; which may easily be prevented by keeping the ball under water, or by using oil only in working the pump and condenser.

"In this manner, I have found by repeated trials, when the heat of the air has been above 50°, and the mercury at a mean height in the barometer, that the water will expand and rise in the tube by removing the weight of the atmosphere four divisions and $\frac{6}{10}$; or one part in 21,740; and will be as much compressed under the weight of an additional atmosphere. Therefore the compression of water by twice the weight of the atmosphere, is one part in 10,870 of its whole bulk.

"The famous Florentine experiment, which so many philosophical writers have mentioned as a proof of the incompressibility of water, will not, when carefully considered, appear sufficient for that purpose: for in forcing any part of the water contained in a hollow globe of gold through its pores by pressure, the figure of the gold must be altered, and consequently the internal space containing the water diminished; but it was impossible for the gentlemen of the academy *del Cimento* to determine, that the water which was forced into the pores and through the gold, was exactly equal to the diminution of the internal space by the pressure."

An easy confirmation of this doctrine of Mr Canton's would be, to fill a vial exactly with water taken up at a great depth, by a perton in a diving bell. If the water at that depth was really compressed by what lay above it, it must expand during its ascent to the surface, and either break the vial, or drive out the stopper.

Hard WATER. By this name is understood such water as will not entirely dissolve soap, but produces a white or greyish coagulum, more or less in quantity in proportion to the hardness of the water. Formerly the hardness of waters was thought to be occasioned by sea-salt: but Dr Home in his Treatise on Bleaching, shows, that this salt can never make water hard, nor indeed can it be done by any perfect neutral, unless mixed in very large quantity with the water. On the other hand, acids of all kinds, imperfect neutrals, and ammoniacal salts, will harden water. The reason of this is, that the alkali of the soap has a less attraction for the oil with which it is united than with the acid, and therefore leaves the oil in order to unite with it; and it is the oil thus separated which we see floating like a curd in hard water when soap is mixed with it. From this theory we have an easy method of softening hard waters; viz. by dissolving in them a quantity of fixed alkali sufficient to absorb the acid, after which it can have no more effect in separating the oil which makes part of the soap. The most common substances by which waters are rendered hard, are selenites and calcareous nitre. From the former they may in good measure be freed by boiling; but not from the latter,

nor from any imperfect salt which readily dissolves in water.

Holy WATER, a water prepared every Sunday in the Romish church, with divers prayers, exorcisms, &c. used by the people to cross themselves withal at their entrance to and going out of church; and pretended to have the virtue of washing away venial sins, driving away devils, preserving from thunder, dissolving charms, securing from, or curing diseases, &c. Many of the Reformed take the use of holy water to have been borrowed from the lustral water of the ancient Romans.

Medicinal WATERS are generally impregnated with iron dissolved in the acridal acid or fixed air, with vitriol, sulphur, bitumen, &c. in consequence of which they produce various effects on the human body. The following directions for analysing them are given by Dr Lettison.

"As many springs contain a volatile principle soon liable to be dissipated, it is necessary to make our experiments on the spot, in order to discover the contents of such waters. Various as these contents may at first appear, the apparatus proper to detect all of them may be reduced into a very small compass.

"When we propose to examine any medicinal spring, the soil and face of the country should be considered, the stony or mineral appearance, and particularly whether there are any mineral veins; the degree of heat of the water should be ascertained by a thermometer, and its comparative weight to other springs in the neighbourhood also carefully observed; after which we may enter on our experiments.

"I. *Aërial Matters.* 1. **MEPHITIC**, fixable, or fixed air, is heavier than common or vital air, and frequently mixed with water; by which union common water is capable of dissolving iron, and thereby forming a chalybeate spring, as in Pyrmont, Spa, and many other celebrated mineral waters.

"This mephitic air is detected by lime-water; the former precipitating the calcareous earth of the latter in a white powder. To discover the quantity of this ærial matter, a bottle filled with the mineral water should be tied over the mouth with a loose bladder: the bottle is then to be placed in boiling water, the heat whereof will extricate the mephitic air, which rising into the bladder, may be collected by tying the bladder close to the neck of the bottle, and afterwards measured by a proportionable bulk of water.

"II. *Saline Bodies.* 1. An acid is sometimes found in the composition of mineral waters, which is always the vitriolic.

"a. In its fixed state, which is supposed to be separated from pyrites: this is however very rare, and probably never occurs, as it cannot remain long in this state without being neutralised by earths, salts, or metals.—Many of those springs called *acidule*, received this name from the mephitic air we have already mentioned. If this acid be present, it may be discovered by an infusion of syrup of violets, or by an infusion of lacmus, or archil, which are turned of a brighter or reddish colour by it. This acid may be detected also by a solution of lead in the nitrous acid; the solution should be fully saturated. The nitrous acid uniting with calcareous earth, or fossil alkali, falls in a white sediment,

Naturalists and Travellers Companion.

Water.

sediment, while the vitriolic acid combines with the lead.

" b, In its volatile sulphureous state.

" 2. An alkali is also very seldom found in water in its proper state.

" When a fossil alkali is present, it is more nicely detected by the syrup of violets, or infusion of lacmus, than the former, these being turned green by the least portion of alkali. If a considerable quantity of alkali were combined with the water, it might be precipitated by a solution of calcareous earth, or by acids.

" A volatile alkali may be distinguished by a solution of corrosive sublimate mercury in water, or in the nitrous acid, the alkali rendering the solution white, a precipitation of a white powder ensues; but no change is produced when the alkali is the fixed or fossil; or if any, the mercury will be precipitated in an orange, brown, or reddish powder; where there is a considerable quantity of the volatile alkali, the water turns blue by the addition of copper. When this alkali is in a very small proportion, some of the water should be distilled over.

" 3. Neutral salts are frequently found in medicinal waters.

" Glauber's salt, compounded of vitriolic acid, and fixed fossil alkali; spirit of wine added to a solution of this salt precipitates it in a white powder; but no change is produced by the addition of any alkaline salt.

" Epsom salt, formed of the same acid, and the earth of magnesia, is often a composition in purging waters. Any alkaline salt, either fixed or volatile, turns this water milky or curdly; the alkaline salt uniting with the vitriolic acid precipitates the earth of magnesia.

" Nitre is composed of the nitrous acid and fixed alkali. Water containing this salt should be evaporated, and the nitre remaining may be known by deflagration, or by its making a crackling noise over the fire. When the nitrous acid is combined with calcareous earth instead of the fixed alkali, the earth may be precipitated by the addition of this alkali.

" Common salt, consisting of the muriatic acid, and fossil alkaline salt. The acid of this salt is nicely detected by a solution of silver in the nitrous acid; the muriatic acid having a nearer affinity with silver than the nitrous, unites with the silver, which falls down in a white sediment, while the nitrous acid joins with the alkali of the common salt. It is proper to have a redundancy of the nitrous acid in the solution of silver, lest the silver be precipitated by a calcareous earth which may be in the water.

" III. *Earthy Substances.* CALCAREOUS earth, or calcined lime-stone, is found in most wells and medicinal springs; the presence of which is best discovered by a solution of lead in the nitrous acid. This acid should be saturated with as much lead as it will dissolve, lest the superfluous acid should saturate the earth and prevent the precipitation of the lead. If there be any calcareous earth in the water, this solution turns it milky, and after some time a white powder is deposited, the calcareous earth precipitating the lead, by uniting with the nitrous acid.

" If calcareous earth be suspended in water by combination with the vitriolic acid, gypsum or selenites is formed, which may be discovered by the addition of

Water.

alkaline salt to this compound; the mixture should be warmed a little, to promote the precipitation of the selenitic earth.

" The same acid united with argillaceous earth, or earth of alum, produces an aluminous austere composition; and the earth may be precipitated also by alkaline salt, which uniting with the vitriolic acid, allows the earth to fall down in a sediment.

" IV. *Sulphureous.* SULPHUR may be suspended in its proper form, tho' it is not soluble in this state: but when the principle of inflammability in sulphur is combined with calcareous earth, or any alkali, in the form of an hepar sulphuris, it readily dissolves; in which case the water smells disagreeably, like the scourings of a gun, or putrid eggs. It is distinguished also by a solution of saccharum saturni (sugar of lead) in the nitrous or vegetable acids: a little of this solution being marked in lines on paper, and the paper suspended over the water, the volatile sulphureous fumes arising from the water turn these lines of a brown or dark colour; the inflammable matter of the sulphur uniting with the lead in the solution of the saccharum saturni, partly revives the metal, and hence produces that dark colour.

" V. *Bituminous Bodies.* BITUMEN frequently runs from amongst rocks, whence it is called *petroleum*; it is also common in the bowels of the earth, as hath been often fatally experienced from those bituminous vapours called *fire-damps*, which prove inflammable, and therefore differ from mephitic air, the latter extinguishing fire. Whether this inflammable vapour is formed of the principle of inflammability of sulphur and the vitriolic acid in a volatile state, is not so well ascertained as the remarkable effects produced by these bituminous bodies in the mountains of *Ætna*, *Vesuvius*, and many others mentioned in history.

" Liquid bitumen, naphtha, or petroleum, is never found combined with water, but floats on its surface in a manner evident to the eye, and may be particularly distinguished by the taste and smell.

" VI. *Metallic Substances.* IRON is a common ingredient in mineral waters, whence they are called *chalybeate*. The general method of distinguishing this metal is by an infusion of powder of galls, which turns water containing iron of a purple or black colour, deeper in proportion to the quantity of iron present.

" But the most accurate method is by means of the Prussian alkali fully saturated with the inflammable matter of dried blood. This alkali mixed with a chalybeate water turns the latter immediately blue, and deposits the iron in a powder of the same colour.

" Copper in water is precipitated in a red powder by the same alkali.

" Zinc is precipitated in a white powder by the Prussian alkali. Although this alkali precipitates all the metallic substances from acids, so that they may be distinguished from one another, it does not any of the earths.

" Arsenic has been suspected in some mineral springs, but I am acquainted with no proof of it. However, it may possibly happen that water running through arsenical veins may carry off a quantity of arsenic. To discover this, the water should be evaporated, and the residuum may be placed on a hot bar of iron; and if there be any arsenic, it is known by emitting

emitting a strong garlic-like smell: or this residuum may be moistened with oil, and put between two bright plates of copper; which, when heated, are turned of a white colour if any arsenic be present: but the smell generally affords a sufficient test."

Rain-Water may be looked upon as the purest distilled water, but impregnated during its passage thro' the air with a considerable quantity of phlogistic and putrescent matter; whence it is superior to any other in fertilizing the earth. Hence also it is inferior for domestic purposes to spring or river-water, even if it could be readily procured; but such as is got from spouts placed below the roofs of houses, the common way of procuring it in this country, is evidently very impure, and becomes putrid in a short time.

River or Running Water, is next in purity to snow or distilled water; and for domestic purposes superior to both, in having less putrescent matter, and more fixed air. Such water, however, is to be chosen as runs in a clear stream through a rocky or stony channel; such as passes over mud, clay, or mossy ground, being impregnated with some part of these substances. The water of large rivers which run slowly is apt to be putrescent.

Putrid Water, is that which has acquired an offensive smell and taste by the putrescence of animal or vegetable substances contained in it. It is in the highest degree pernicious to the human frame, and capable of bringing on mortal diseases even by its smell. It is not always from the apparent muddiness of waters that we can judge of their disposition to putrefy; some which are seemingly very pure being more apt to become putrid than others which appear much more mixed with heterogeneous matters. Under the article *ANIMALCULE*, n° 33, is mentioned a species of insects which have the property of making water stink to an incredible degree, though their bulk in proportion to the fluid which surrounds them, is less than that of one to a million. Other substances no doubt there are which have the same property; and hence almost all water which is kept confined from the air is apt to become offensive, even though kept in glass or stone ware vessels. Indeed it is a common observation, that water keeps much longer sweet in earthen or stone ware vessels than in glass; but of all others it is most apt to putrefy in those of wood. Hence, as ships can only be supplied with water kept in wooden casks, sailors are extremely liable to those diseases which arise from putrid water; and the discovery of a method by which water could easily be prevented from becoming putrid at sea would be exceedingly valuable. This may indeed be done by quicklime; for when water is impregnated with it, all putrescent matters are either totally destroyed, or altered in such a manner as never to be capable of undergoing the putrefactive fermentation again. But a continued use of lime-water could not fail of being pernicious, and it is therefore necessary to throw down the lime; after which the water will have all the purity necessary for preserving it free from putrefaction. This can only be done by means of fixed air; and mere exposure in broad shallow vessels to the atmosphere would do it without any thing else, only taking care to break the crust which formed upon it. Two methods, however, have been thought of for doing this with more expedition. The one, invented by

Dr Alston, is, by throwing into the water impregnated with lime a quantity of magnesia. The lime attracts fixed air more powerfully than magnesia, in consequence of which the latter parts with it to the lime; which thus becoming insoluble, falls along with the caustic magnesia to the bottom, and thus leaves the water perfectly pure. Another method is that of Mr Henry, who proposes to throw down the lime by means of an effervescing mixture of oil of vitriol and chalk put down to the bottom of the water-cask. His apparatus for this purpose is as simple as it can well be made, though it is hardly probable that sailors will give themselves the trouble of using it; and Dr Alston's scheme would seem better calculated for them, were it not for the expence of the magnesia; which indeed is the only objection made to it by Mr Henry. Putrid water may be restored and made potable by a process of the same kind.

Sea-Water is a solution of common salt, sal catharticus anarus, a selenitic substance, and a compound of muriatic acid with magnesia, mixed together in various proportions. It may be freshened by simple distillation without any addition; a discovery for which we are indebted to Dr Lind. Sea-water by itself has a purgative quality, owing to the salts it contains; and has been greatly recommended in scrophulous disorders. Externally applied, sea-water is more powerful than common water, by reason of its superior cohesiveness and specific gravity.

Spring-Water is commonly impregnated with a small portion of imperfect neutral salt, extracted from the different strata through which it percolates. Some contain a vast quantity of stony matter, which they deposit as they run along, and thus form masses of stone; sometimes incrustating various animal and vegetable matters, which they are therefore said to petrify. Spring-water is much used for domestic purposes, and on account of its coolness is an agreeable drink; but on account of its being generally somewhat hard, is inferior to that which has run for a considerable way in a channel.

Water-Engine, or engine for extinguishing fires. See *HYDROSTATICS*, n° 33.

Water-Ordeal. See *ORDEAL*.

Water, among jewellers, is properly the colour or lustre of diamonds and pearls. The term, though less properly, is sometimes used for the hue or colour of other stones.

Water-Bellows. See *Machines for blowing Air into Furnaces*.

Water-Colours, in painting, are such colours as are only diluted and mixed up with gum-water, in contradistinction to oil-colours. See *COLOUR-Making*.

Water-Gang, a channel cut to drain a place by carrying off a stream of water.

Water-Line of a Ship, certain horizontal lines supposed to be drawn about the outside of a ship's bottom, close to the surface of the water in which the floats. They are accordingly higher or lower upon the bottom, in proportion to the depth of the column of water required to float her. See *SHIP-buildings*, Part I.

Water Lodged, the state of a ship when, by receiving a great quantity of water into the hold, by leaking, &c. she has become heavy and inactive upon the sea,

sea, so as to yield without resistance to the efforts of every wave rushing over her decks. As, in this dangerous situation, the centre of gravity is no longer fixed, but fluctuating from place to place, the stability of the ship is utterly lost : she is therefore almost totally deprived of the use of her sails, which would operate to overfet her, or press the head under water. Hence there is no resource for the crew, except to free her by the pumps, or to abandon her by the boats as soon as possible.

Water-Sail, a small sail spread occasionally under the lower studding-sail, or driver-boom, in a fair wind and smooth sea.

Water-Spout, an extraordinary and dangerous meteor, consisting of a large mass of water, collected into a sort of column by the force of a whirlwind, and moved with rapidity along the surface of the sea.

A variety of authors have written on the cause and effects of these meteors, with different degrees of accuracy and probability.

Dr Franklin, in his physical and meteorological observations, supposes a water-spout and a whirlwind to proceed from the same cause ; their only difference being, that the latter passes over the land, and the former over the water. This opinion is corroborated by M. de la Pyrme, in the Philosophical Transactions, where he describes two spouts observed at different times in Yorkshire, whose appearances in the air were exactly like those of the spouts at sea, and their effects the same as those of real whirlwinds.

Whirlwinds have generally a progressive as well as circular motion ; so had what is called the spout at Topsham, described in the Transactions ; and this also by its effects appears to have been a real whirlwind.—Water-spouts have also a progressive motion, which is more or less rapid ; being in some violent, and in others barely perceptible.

Whirlwinds generally rise after calms and great heats : the same is observed of water-spouts, which are therefore most frequent in the warm latitudes.

The wind blows every way from a large surrounding place to a whirlwind. Three vessels, employed in the whale-fishery, happening to be becalmed, lay in sight of each other, at about a league distance, and in the form of a triangle. After some time a water-spout appeared near the middle of the triangle ; when a brisk gale arose, and every vessel made sail. It then appeared to them all by the trimming of their sails, and the course of each vessel, that the spout was to leeward of every one of them ; and this observation was further confirmed by the comparing of accounts when the different observers afterwards conferred about the subject. Hence whirlwinds and water-spouts agree in this particular likewise.

But if the same meteor, which appears a water-spout at sea, should, in its progressive motion, encounter and pass over land, and there produce all the phenomena and effects of a whirlwind, it would afford a stronger conviction that a whirlwind and a water-spout are the same thing. An ingenious correspondent of Dr Franklin gives one instance of this that fell within his own observation.

“ I had often seen (says he) water-spouts at a distance, and heard many strange stories of them, but never knew any thing satisfactory of their nature or cause, until

that which I saw at Antigua ; which convinced me that a water-spout is a whirlwind, which becomes visible in all its dimensions by the water it carries up with it.

There appeared, not far from the mouth of the harbour of St John's, two or three water-spouts, one of which took its course up the harbour. Its progressive motion was slow and unequal, not in a straight line, but as it were by jerks or flans. When just by the wharf, I stood about 100 yards from it. There appeared in the water a circle of about 20 yards diameter, which to me had a dreadful though pleasing appearance. The water in this circle was violently agitated, being whisked about, and carried up into the air with great rapidity and noise, and reflected a lustre, as if the sun shined bright on that spot, which was more conspicuous, as there appeared a dark circle around it. When it made the shore, it carried up with the same violence shingles, flaves, large pieces of the roofs of houses, &c. and one small wooden house it lifted entirely from the foundation on which it stood, and carried it to the distance of 14 feet, where it settled without breaking or oversetting ; and, what is remarkable, though the whirlwind moved from west to east, the house moved from east to west. Two or three negroes and a white woman were killed by the fall of the timber, which it carried up into the air, and dropped again. After passing through the town, I believe it was soon dissipated ; for, except tearing a large limb from a tree, and part of the cover of a sugar-work near the town, I do not remember any further damage done by it.”

A fluid moving from all points horizontally towards a centre, must at that centre either mount or descend. If a hole be opened in the middle of the bottom of a tub filled with water, the water will flow from all sides to the centre, and there descend in a whirl : but air flowing on or near the surface of land or water, from all sides towards a centre, must at that centre ascend ; because the land or water will hinder its descent.

If these concentrating currents of air be in the upper region, they may indeed descend in the spout or whirlwind ; but then, when the united current reached the earth or water, it would spread, and probably blow every way from the centre. There may be whirlwinds of both kinds ; but from the effects commonly observed, Dr Franklin suspects the rising one to be most frequent : when the upper air descends, it is perhaps in a greater body, extending wider, as in thunder-gusts, and without much whirling ; and when air descends in a spout or whirlwind, he conceives that it would rather press the roof of a house inwards, or force in the tiles, shingles, or thatch, and force a boat down into the water, or a piece of timber into the earth, than snatch them upwards, and carry them away.

The whirlwinds and spouts are not always, though most frequently, in the day-time. The terrible whirlwind which damaged a great part of Rome, June 11, 1749, happened in the night, and was supposed to have been previously a water-spout, it being asserted as an undoubted fact, that it gathered in the neighbouring sea, because it could be traced from Ostia to Rome.

This whirlwind is said to have appeared as a very black, long, and lofty cloud, discoverable, notwithstanding the darkness of the night, by its continually lightning, or emitting flashes on all sides, pushing a-

Water. long with a surprising swiftness, and within three or four feet of the ground. Its general effects on houses were, stripping off the roofs, blowing away chimnies, breaking doors and windows, forcing up the floors, and unpaving the rooms; and the very rafters of the houses were broke and dispersed, and even hurled against houses at a considerable distance, &c.

The Doctor, in proceeding to explain his conceptions, begs to be allowed two or three positions, as a foundation for his hypothesis. 1. That the lower region of air is often more heated, and so more rarified, than the upper, and by consequence specifically lighter. The coldness of the upper region is manifested by the hail, which sometimes falls from it in warm weather. 2. That heated air may be very moist, and yet the moisture so equally diffused and rarified as not to be visible till colder air mixes with it; at which time it condenses and becomes visible. Thus our breath, although invisible in summer, becomes visible in winter.

These circumstances being granted, he presupposes a tract of land or sea, of about 60 miles in extent, unsheltered by clouds and unrefreshed by the wind, during a summer's day, or perhaps for several days without intermission, till it becomes violently heated, together with the lower region of the air in contact with it; so that the latter becomes specifically lighter than the superincumbent higher region of the atmosphere, wherein the clouds are usually floated: he supposes also that the air surrounding this tract has not been so much heated during those days, and therefore remains heavier. The consequence of this, he conceives, should be, that the heated lighter air should ascend, and the heavier descend; and as this rising cannot operate throughout the whole tract at once, because that would leave too extensive a vacuum, the rising will begin precisely in that column which happens to be lightest or most rarified; and the warm air will flow horizontally from all parts to this column, where the several currents meeting, and joining to rise, a whirl is naturally formed, in the same manner as a whirl is formed in a tub of water, by the descending fluid receding from all sides of the tub towards the hole in the centre.

And as the several currents arrive at this central rising column, with a considerable degree of horizontal motion, they cannot suddenly change it to a vertical motion; therefore as they gradually, in approaching the whirl, decline from right to curve or circular lines, so, having joined the whirl, they ascend by a spiral motion: in the same manner as the water descends spirally through the hole in the tub before mentioned.

Lastly, as the lower air nearest the surface is more rarified by the heat of the sun, it is more impressed by the current of the surrounding cold and heavy air which is to assume its place, and consequently its motion towards the whirl is swiftest, and so the force of the lower part of the whirl strongest, and the centrifugal force of its particles greatest. Hence the vacuum which incloses the axis of the whirl should be greatest near the earth or sea, and diminish gradually as it approaches the region of the clouds, till it ends in a point.

This circle is of various diameters, sometimes very large.

If the vacuum passes over water, the water may rise

in a body or column therein to the height of about 32 feet. This whirl of air may be as invisible as the air itself, though reaching in reality from the water to the region of cool air, in which our low summer thunder-clouds commonly float; but it will soon become visible at its extremities. The agitation of the water under the whirling of the circle, and the swelling and rising of the water in the commencement of the vacuum, renders it visible below. It is perceived above by the warm air being brought up to the cooler region, where its moisture begins to be condensed by the cold into thick vapour, and is then first discovered at the highest part, which being now cooled condenses what rises behind it, and this latter acts in the same manner on the succeeding body; where, by the contact of the vapours, the cold operates faster in a right line downwards, than the vapours themselves can climb in a spiral line upwards: they climb, however; and as by continual addition they grow denser, and by consequence increase their centrifugal force, and being risen above the concentrating currents that compose the whirl, they fly off, and form a cloud.

It seems easy to conceive, how, by this successive condensation from above, the spout appears to drop or descend from the cloud, although the materials of which it is composed are all the while ascending. The condensation of the moisture contained in so great a quantity of warm air as may be supposed to rise in a short time in this prodigiously rapid whirl, is perhaps sufficient to form a great extent of cloud; and the friction of the whirling air on the sides of the column may detach great quantities of its water, disperse them into drops, and carry them up in the spiral whirl mixed with the air. The heavier drops may indeed fly off, and fall into a shower about the spout; but much of it will be broken into vapour, and yet remain visible.

As the whirl weakens, the tube may apparently separate in the middle; the column of water subsiding, the superior condensed part drawing up to the cloud. The tube or whirl of air may nevertheless remain entire, the middle only becoming invisible, as not containing any visible matter.

Dr Stuart, in the Philosophical Transactions, says, "It was observable of all the spouts he saw, but more perceptible of a large one, that towards the end it began to appear like a hollow canal, only black in the borders, but white in the middle; and though it was at first altogether black and opaque, yet the sea-water could very soon after be perceived to fly up along the middle of this canal like smoke in a chimney."

When Dr Stuart's spouts were full charged, that is, when the whirling pipe of air was filled with quantities of drops and vapour torn off from the column, the whole was rendered so dark that it could not be seen through, nor the spiral ascending motion discovered; but when the quantity ascending lessened, the pipe became more transparent, and the ascending motion visible. The spiral motion of the vapours, whose lines intersect each other on the nearest and furthest side of this transparent part, appeared therefore to Stuart like smoke ascending in a chimney; for the quantity being still too great in the line of sight through the sides of the tube, the motion could not be discovered there, and so they represented the solid sides of the chimney.

Water.

Water
||
Watering.

Dr Franklin concludes by supposing a whirlwind or spout to be stationary, when the concurring winds are equal; but if unequal, the whirl acquires a progressive motion in the direction of the strongest pressure. When the wind that communicates this progression becomes stronger above than below, or below than above, the spout will be bent or inclined. Hence the horizontal process and obliquity of water-spouts are derived. See WHIRLWIND.

WATER-works, in general, denote all manner of machines moved by or employed in raising or sustaining water. See **HYDROSTATICS** including **HYDRAULICS**.

WATER-Works for entertainment. See **HYDROSTATICS**, chap. iv.

WATERFORD, a county of Ireland in the province of Munster, bounded on the west by the county of Cork; on the south by the ocean; on the north by the river Sure, which parts it from the county of Tipperary and Kilkenny; and on the east by its own haven, which parts it from the county of Wexford. Its greatest length, according to some, is 46 miles, but according to others only 38; and its breadth 24. It contains 259,000 acres, and six baronies. The members it sends to parliament are two knights for the shire, and two burgesses a-piece for Waterford city, Lismore, Dungarvan, and Tallagh.

Waterford, capital of the county of the same name, standing upon the river Sure, was first built by certain pirates of Norway, and hath been a bishop's-see ever since the year 1096, when these pirates, who had embraced Christianity, sent Malchus, a benedictine monk of Winchester, to be consecrated their bishop by Anselm, archbishop of Canterbury. Till it was eclipsed by Cork, it was accounted the second city in the kingdom for trade, wealth, and populousness, being situated on a fine harbour, defended by Duncannon fort on the east side. The soil, however, about it is barren, and the air thick. Many considerable privileges have been conferred upon it by the kings of England, as a reward for its constant fidelity, since it was first reduced by Richard earl of Pembroke. During the Irish rebellion it was in the hands of the rebels, who often made excursions from it, and committed great outrages; but Oliver Cromwell reduced it in 1650. The Popish party got possession of it also in 1689, and held it till after the battle of Boyne. Here is a fine cathedral; but the houses are generally of timber, and make but a mean appearance. The city drives a great trade, particularly with England, and ships of burden come up close to its fine key. Waterford haven extends near eight miles and a half from south to north, almost in a straight line, all the way deep and clear, and but little incumbered with rocks or sand. The city and its liberties make a distinct county. There is a citadel on the west side, and on the east a block-house and store-house. Waterford, jointly with Wexford, or Weisford, gives the title of earl to the earl of Suresbury in England, and is the county town.

WATERING, in the manufactures, is to give a lustre to stuffs, &c. by wetting them lightly with gum-water, and then passing them through the press or calender whether hot or cold. The gum-water ought to be pure, thin, and clear, otherwise the folds of the stuff will all stick together: the operation must also be performed when the water is very hot, that it may penetrate.

Waterland
||
Wave.

WATERLAND (Dr Daniel), a learned English divine who distinguished himself greatly in theological controversies, was born in 1683 at Wafely in Lincolnshire, of which place his father was rector. He had his academical learning at Magdalen college, Cambridge, where he drew up a useful tract which went through several editions, intitled, *Advice to a young Student, with a Method of Study for the first four years*. In 1713 he became master of the college, was soon after appointed chaplain to George I. and in 1720, preached the first course of lectures founded by Lady Moyer in defence of our Lord's divinity. He went through several promotions; and at the time of his death in 1740, was canon of Windsor, archdeacon of Middlesex, and vicar of Twickenham. Besides his controversial writings, he published two volumes of sermons.

WATTS (Dr Isaac), a learned and eminent dissenting minister, was born at Southampton in 1674, of parents eminent for piety, and considerable sufferers for conscience-sake. In 1690 he was sent up to London for academical education, under the tuition of the Rev. Mr Thomas Rowe; and in 1696 was himself engaged as tutor to the son of Sir John Hartopp, bart. at Stoke Newington. He began to preach in 1698, and met with general acceptance; and after officiating for three years as an assistant to the Rev. Dr Isaac Chauncy, he succeeded him in his pastoral charge in 1702, and continued to preside over that church as long as he lived. Though his whole income did not amount to an hundred a-year, he allotted one-third of it to the poor. He died in 1748. His numerous works have rendered his name famous among people of every denomination, both in this and other countries, and they have been translated into a variety of languages. His Lyric Poems, his Psalms and Hymns, and his divine Songs for Children, are a sufficient proof of his poetical talents, and have had an amazing number of editions. His logic and philosophy have been much admired. He also wrote works upon a variety of other subjects, and printed several volumes of his sermons. He was admired for the mildness and benevolence of his disposition, and the sweetness of his manners. After his death, his works were collected, and published in 6x volumes quarto.

WATLING-STREET. See **WAY**.

WAVE, in philosophy, a cavity in the surface of water, or other fluids, with an elevation aside thereof.

The waves of the sea are of two kinds, natural and accidental. The natural waves are those which are exactly proportioned in size to the strength of the wind, whose blowing gives origin to them. The accidental waves are those occasioned by the wind's reacting upon itself by repercussion from hills and mountains, or high shores, and by the washing of the waves themselves; otherwise of the natural kind, against rocks and shoals: all these cases give the waves an elevation, which they can never have in their natural state.

Mr Boyle has proved, by numerous experiments, that the most violent wind never penetrates deeper than six feet into the water; and it should seem a natural consequence of this, that the water moved by it can only be elevated to the same height of six feet from the level of the surface in a calm: and this six feet of elevation being added to the six of excavation,

Wave. in the part whence that water so elevated was raised, should give twelve feet for the utmost elevation of a wave. This is a calculation that does great honour to its author: for count Marfigi measured carefully the elevation of the waves near Provence, and found, that in a very violent tempest they arose only to seven feet above the natural level of the sea; and this additional foot in height he easily resolved into the accidental shocks of the water against the bottom, which was, in the place he measured them in, not so deep as to be out of the way of affecting the waves; and he allows that the addition of one-sixth of the height of a wave, from such a disturbance from the bottom, is a very moderate alteration from what would have been its height in a deep sea; and concludes, that Mr Boyle's calculation holds perfectly right in deep seas, where the waves are purely natural, and have no accidental causes to render them larger than their just proportion. In deep water, under the high shores of the same part of France, this author found the natural elevation of the waves to be only five feet; but he found also, that their breaking against rocks, and other accidents to which they were liable in this place, often raised them to eight feet high.

We are not to suppose, from this calculation, that no wave of the sea can rise more than six feet above its natural level in open and deep water; for waves immensely higher than these are formed in violent tempests in the great seas. This, however, are not to be accounted waves in their natural state; but they are single waves formed of many others: for in these wide plains of water, when one wave is raised by the wind, and would elevate itself up to the exact height of six feet, and no more, the motion of the water is so great, and the succession of the waves so quick, that, during the time this is rising, it receives into it several other waves, each of which would have been at the same height with itself; these run into the first wave, one after another, as it is rising; by this means its rise is continued much longer than it naturally would have been, and it becomes terribly great. A number of these complex waves arising together, and being continued in a long succession by the continuation of the storm, make the waves so dangerous to ships, which the sailors in their phrase call *mountain-high*.

Stilling WAVES by means of oil. This wonderful property, though well known to the ancients, as appears from the writings of Pliny, was for many ages either quite unnoticed, or treated as fabulous by succeeding philosophers. Of late it has, by means of Dr Franklin, again attracted the attention of the learned; though from some anecdotes it appears that the vulgar have always been acquainted with it. In Martin's description of the Western Islands of Scotland, we have the following passage: "The steward of Kilda, who lives in Pabbay, is accustomed, in time of a storm, to tie a bundle of puddings, made of the fat of sea-fowl, to the end of his cable, and lets it fall into the sea behind his rudder. This, he says, hinders the waves from breaking, and calms the sea." Mr Pennant in his *British Zoology*, vol. iv. under the article *Seal*, takes notice, that when these animals are devouring a very oily fish, which they always do under water, the waves above are remarkably smooth; and by this mark the fishermen know where to find them.

Sir Gilbert Lawton, who served long in the army at Gibraltar, assured Dr Franklin, that the fishermen in that place are accustomed to pour a little oil on the sea, in order to still its motion, that they may be enabled to see the oysters lying at its bottom, which are there very large, and which they take up with a proper instrument. A similar practice obtains among fishermen in various other parts, and Dr Franklin was informed by an old sea-captain, that the fishermen of Lisbon, when about to return into the river, if they saw too great a surf upon the bar, to empty a bottle or two of oil into the sea, which would suppress the breakers, and allow them to pass freely.

The Doctor having revolved in his mind all these pieces of information, became impatient to try the experiment himself. At last having an opportunity of observing a large pond very rough with the wind, he dropped a small quantity of oil upon it. But having at first applied it on the lee-side, the oil was driven back again upon the shore. He then went to the windward side, and poured on about a tea-spoonful of oil. This produced an instant calm over a space several yards square, which spread amazingly, and extended itself gradually till it came to the lee-side; making all that quarter of the pond, perhaps half an acre, as smooth as glass. This experiment was often repeated in different places, and always with success. Our author accounts for it in the following manner:

"There seems to be no natural repulsion between water and air, to keep them from coming into contact with each other. Hence we find a quantity of air in water; and if we extract it by means of the air pump, the same water again exposed to the air will soon imbibe an equal quantity.—Therefore air in motion, which is wind, in passing over the smooth surface of water, may rub as it were upon that surface, and raise it into wrinkles; which if the wind continues, are the elements of future waves. The smallest wave once raised does not immediately subside and leave the neighbouring water quiet; but in subsiding raises nearly as much of the water next to it, the friction of the parts making little difference. Thus a stone dropped in a pool raises first a single wave round itself, and leaves it, by sinking to the bottom; but that first wave subsiding raises a second, the second a third, and so on in circles to a great extent.

"A small power continually operating, will produce a great action. A finger applied to a weighty suspended bell, can at first move it but little; if repeatedly applied, though with no greater strength, the motion increases till the bell swings to its utmost height, and with a force that cannot be resisted by the whole strength of the arm and body. Thus the small first raised waves being continually acted upon by the wind, are, though the wind does not increase in strength, continually increased in magnitude, rising higher and extending their bases, so as to include a vast mass of water in each wave, which in its motion acts with great violence. But if there be a mutual repulsion between the particles of oil, and no attraction between oil and water, oil dropped on water will not be held together by adhesion to the spot whereon it falls; it will not be imbibed by the water; it will be at liberty to expand itself; and it will spread on a surface that, besides being smooth to the most perfect degree of polish, pre-

Waved. vents, perhaps by repelling the oil, all immediate contact, keeping it at a minute distance from itself; and the expansion will continue, till the mutual repulsion between the particles of the oil is weakened and reduced to nothing by their distance.

"Now I imagine that the wind blowing over water thus covered with a film of oil cannot easily catch upon it, so as to raise the first wrinkles, but slides over it, and leaves it smooth as it finds it. It moves a little the oil indeed, which being between it and the water, serves it to slide with, and prevents friction, as oil does between those parts of a machine that would otherwise rub hard together. Hence the oil dropped on the windward side of a pond proceeds gradually to leeward, as may be seen by the smoothness it carries with it quite to the opposite side. For the wind being thus prevented from raising the first wrinkles that I call the *elements of waves*, cannot produce waves, which are to be made by continually acting upon and enlarging those elements; and thus the whole pond is calmed.

"Totally therefore we might suppress the waves in any required place, if we could come at the windward place where they take their rise. This in the ocean can seldom if ever be done. But perhaps something may be done on particular occasions to moderate the violence of the waves when we are in the midst of them, and prevent their breaking where that would be inconvenient. For when the wind blows fresh, there are continually rising on the back of every great wave a number of small ones, which roughen its surface, and give the wind hold, as it were, to push it with greater force. This hold is diminished by preventing the generation of those small ones. And possibly too, when a wave's surface is oiled, the wind, in passing over it, may rather in some degree press it down, and contribute to prevent its rising again, instead of promoting it.

"This, as mere conjecture would have little weight, if the apparent effects of pouring oil into the midst of waves were not considerable, and as yet not otherwise accounted for.

"When the wind blows so fresh, as that the waves are not sufficiently quick in obeying its impulse, their tops being thinner and lighter are pushed forward, broken, and turned over in a white foam. Common waves lift a vessel without entering it; but these when large sometimes break above and pour over it, doing great damage.

"That this effect might in any degree be prevented, or the height and violence of waves in the sea moderated, we had no certain account; Pliny's authority for the practice of seamen in his time being slighted. But discoursing lately on this subject with his excellency count Bentinck of Holland, his son the honourable captain B-tinck, and the learned professor Allemand (to all whom I showed the experiment of smoothing in a windy day the large piece of water at the head of the Green Park), a letter was mentioned which had been received by the Count from Batavia, relative to the saving of a Dutch ship in a storm by pouring oil into the sea."

WAVED, in heraldry, is said of a bordure, or any ordinary or charge, in a coat of arms, having its outlines indented in manner of the rising and falling of waves: it is used to denote, that the first of the family

in whose arms it stands, acquired its honours for service.

WAVING, in the sea-language, is the making signs to a vessel to come near or keep off.

WAX, or *Bees-Wax*, in natural history, a firm and solid substance, moderately heavy, and of a fine yellow colour, formed by the bees from the farina of flowers. See *Apis*.

The best sort is that of a lively yellow colour, and an agreeable smell, somewhat like that of honey: when new, it is toughish, yet easy to break; but by age it becomes harder and more brittle, loses its fine colour, and in a great measure its smell.

From the common yellow wax, by the mere effect of sun and air, or by what is called *bleaching*, is formed what we term *whits-wax*, and some very improperly *virgin wax*. The greater the surface is in proportion to the quantity, the sooner and more perfectly this operation is performed. The usual way is to melt the wax in hot water; when melted, they press it through a strainer of tolerable fine linen, and pour it into round and very shallow moulds. When hardened by cooling, it is taken out and exposed to the sun and air, sprinkling it now and then with water, and often turning it; by this means it soon becomes white. The best sort is of a clear and almost transparent whiteness, dry, hard, brittle, and of an agreeable smell, like that of the yellow wax, but much weaker.

The common yellow wax is of very great use both in medicine and in many of the arts and manufactures. It is sometimes given internally, as in dysenteries and other erosions of the intestines; but its great use is in the making ointments and plasters, and the greater part of those of the shops owe their consistence to it. The white wax is also an ingredient in some of the cerates and ointments of the shops; and is used in making candles, and in many of the nicer arts and manufactures where wax is required.

Sealing-Wax is made in the following manner: Take one pound of bees-wax; three ounces of fine turpentine: olive oil and rosin, finely powdered, of each one ounce: when they are well melted, and the dross taken off, put in an ounce and a half of vermilion, or red-lead, finely ground, and stir them together till they are well incorporated; and when this mixture grows a little cool, roll it into sticks, or in any other form. If you would have it black, instead of vermilion or red-lead, put in lamp-black. The soft, red, and green wax, used in large seals to some of our law-writings, are thus made: Melt bees-wax over a gentle heat, with such a proportion of Venice turpentine as, when cold, will give it the due consistence: this is determined by repeated trials, first putting in but little turpentine, and afterwards more and more, till by dropping a piece upon a marble to cool, it is found of the true consistence. They then colour it with red-lead, or vermilion, or with verditer, or whatever colours they please, the mixture in this state receiving any.

Wax-Work, the representation of the faces, &c. of persons living or dead; made by applying plaster of Paris in a kind of paste, and thus forming a mould containing the exact representation of the features. Into this mould melted wax is poured, and thus a kind of masks are formed; which being painted and set with glass eyes, and the figures dressed in their proper habits,

Waving Wax.

bits, they bear such a resemblance that it is difficult to distinguish between the copy and the original.

WAY, a passage or road.

The Roman ways are divided into consular, prætorian, military, and public; and of these we have four remarkable ones in England: the first, Watling-street, or Watling-freet, leading from Dover to London, Dunstable,oucester, Aterfton, and the Severn, extending as far as Angleica in Wales. The second, called *Hikenild*, or *Ikenild street*, stretches from Southampton over the river Ilis at Newbridge; thence by Camden and Litchfield; then passes the Derwent near Derby, and ends at Tinnmouth. The third, called *Eggesway*, because in some places it was never perfected, but lies as a large ditch, leads from Cornwall through Devonshire, by Tethbury, near Stow in the Wolds; and beside Coventry to Leicester, Newark, and so to Lincoln. The fourth, called *Erming*, or *Erminage-street*, extends from St David's, in Wales, to Southampton.

WAY of a Ship, is sometimes the same as her rake, or run forward or backward: but this term is most commonly understood of her sailing.

WAY-LEAVES, in the coal-business. See COALERY, p. 2030, col. 2.

RIGHT of WAYS, in law. This may be grounded on a special permission; as when the owner of the land grants to another a liberty of passing over his grounds, to go to church, to market, or the like: in which case the gift or grant is particular, and confined to the grantee alone; it dies with the person; and if the grantee leaves the country, he cannot assign over his right to any other; nor can he justify taking another person in his company. A way may be also by prescription; as if all the owners and occupiers of such a farm have immemorially used to cross another's ground; for this immemorial usage supposes an original grant, whereby a right of way thus appurtenant to land may clearly be created. A right of way may also arise by act and operation of law; for if a man grants me a piece of ground in the middle of his field, he at the same time tacitly and impliedly gives me a way to come at it; and I may cross his land for that purpose without trespass. For when the law doth give any thing to one, it giveth impliedly whatsoever is necessary for enjoying the same. By the law of the twelve tables at Rome, where a man had the right of way over another's land, and the road was out of repair, he who had the right of way might go over any part of the land he pleased: which was the established rule in public as well as private ways. And the law of England, in both cases, seems to correspond with the Roman.

WAY-WADE, a title given to the governors of the chief places in the empire of Muscovy and in Poland.

WEANING. See AB lactation.

WEAR, or WEER, a great flank or dam in a river, fitted for the taking of fish, or for conveying the stream to a mill. New wears are not to be made, or others altered, to the nuisance of the public, under a certain penalty.

WEASEL, in zoology. See MUSTELA.

WEATHER, the state or disposition of the atmosphere with regard to heat, cold, wind, rain, frost, &c.

WEATHER-COCK, a moveable vane, in form of a cock, or other shape, placed on high, to be turned round ac-

cording to the direction of the wind, and point out the quarter from whence it blows.

WEATHER-GLASSES. See BAROMETER and THERMOMETER.

WEATHERING, among sailors, signifies the doubling or sailing by a head-land or other place.

WEAVING, the art of working a web of cloth, silk, or other stuff, in a loom with a shuttle. For an idea of the manner in which this is performed, see CLOTH.

WEAVING-LOOM, a machine for weaving cloth, silk, &c. by raising the threads of the warp in order to throw in the shoot, and strike it close. Of these there are various kinds, distinguished by the different sorts of cloths, stuffs, silks, &c. in which they are employed; and which are chiefly distinguished by the number and variety of the threads they raise in order to work the warp, either plain or in figures, by making more or less of the woof or shoot appear through the warp. In order to give a general idea of weaving, we shall here describe the parts of the common weaver's loom. See plate CCCXI. fig. 2. in which 9, 9, are the loom-posts. 10. The cross-bars. 11. The batten; which serves to strike in, and close more or less the threads of the woof. 12. The cap of the batten, or a long bar, which the weaver takes hold of in one hand and then in the other. 13. The block, or under part of the same, containing the reed within the lower bar. 14. The cross-piece, or burdon and pin, which helps to make the batten moveable. 15. The gallews; a piece of wood suspending the pulley on which the cord moves that is tied to the two lams. 16. The breast-bar; a flat square piece of wood, with an opening in it to let the stuff through which is rolled on the knee-roll. 17. The cane-roll, which the warp is turned on at the other end of the loom. 18. The reed. 20. Pulleys, upon which the cords roll that are fastened to the lams. 21. The tumbler; which is a cord that passes from one lam to the other over the pulley 20, and causes the working of the lams by its ascending and descending. 22. The muffle in which the pulley acts. 23. A skain, or leish, cut into proper lengths, to mend the leashes of the harness that happen to break. 24. A bobbin of the warp, to mend the threads of the warp that occasionally break. 25. Lizier-thread, to mend those of the lizier that happen to break; and which, especially in cloth, are very different from the warp. 26. The box to hold the quills. 28. The foot-bar. 29. The trundles, or moveable bars, tied with two cords to the lower virgee of each lam. When the foot presses a treadle, the lam that is fastened to it sinks, and the other rises by the help of the tumbler. 30. The foot-step. 31. The temple; a double flat ruler, having small teeth at the extremities; it may be lengthened or shortened by the help of a catch that is in one of the rulers, and introduced in a groove in the other ruler. The teeth in the extremities are fastened in the lizier of the work, by which means it is kept of an equal breadth; and as the work advances the temple is moved forwards. 32. The shuttle seen in front and profile. 33. The knee-roll, on which the work is rolled as it is wove. 34. The tantow; an iron lever to turn the knee-roll. 35. The reed seen separate.

WEB, a sort of tissue or texture formed of threads inter-

Wechel
Weight.

interwoven with each other; some whereof are extended in length, and called the *warps*; others are drawn across, and called the *wwoof*.

WECHEL (Christian), a famous printer in Paris, before the middle of the 16th century. His editions were so extremely correct, that the errata of a folio volume did not sometimes contain above two faults; but he was brought into trouble in 1534, for having fold a book of Erasmus *De usu interdicti Carnium*, which had been censured by the faculty of divinity. According to father Garasse, he fell into poverty, by an immediate curse of God, for printing a book, in which the author endeavoured to prove that innocent children would not be eternally damned for dying without baptism.

WECHEL (Christian and Andrew) two celebrated printers at Francfort, whose editions are correct and much esteemed. They were sons of the former, and owed this perfection of their art to the learned Frederic Sylburgius, corrector of their printing-house. Christian was living in 1552, and Andrew died in 1581. A catalogue of the books which proceeded from their presses was printed at Francfort, in 8vo, in 1590.

WEDGE, one of the mechanical powers. See **MECHANICS**.

WEDNESDAY, the fourth day of the week, so called from a Saxon idol named *Woden*, supposed to be Mars, worshipped on this day.

Ash-WEDNESDAY, the first day of Lent, so called from the custom observed in the ancient Christian church of penitents expressing their humiliation at this time, by appearing in sackcloth and ashes.

WEED, a common name for all rank and wild herbs, that grow of themselves, to the detriment of other useful herbs they grow among.

WEED, in the miners language, denotes the degeneracy of a load or vein of fine metal into an useless marcadite.

WEEK, in chronology, a division of time comprising seven days. See **ASTRONOMY**.

Passion-WEEK, or the *Holy WEEK*, is the last week in Lent, wherein the church celebrates the mystery of our Saviour's death and passion.

WECK or **WYCK**, in geography, a parliament and port-town of Scotland, in the shire of Caithness. W. Long. 2. 45. N. Lat. 58. 40.

WEEVER, in ichthyology. See **TRACHINUS**.

WEIGH, a weight of cheefe, wool, &c. containing 256 pounds averdupois. Of corn, the weigh contains 40 bushels; of barley or malt, six quarters. In some places, as Essex, the weight of cheefe is 300 pounds.

WEIGHING, the act of examining a body in the balance to find its weight.

WEIGHING anchor, is the drawing it out of the ground it had been cast into, in order to set sail, or quit a port, road, or the like.

WEIGHT, in physics, a quality in natural bodies, whereby they tend downwards towards the centre of the earth. Or, weight may be defined in a less limited manner, to be a power inherent in all bodies whereby they tend to some common point, called the *centre of gravity*; and that with a greater or less velocity, as they are more or less dense, or as the medium

they pass through is more or less rare. See **MECHANICS**.

WEIGHT in commerce, denotes a body of a known weight appointed to be put in the balance against other bodies whose weight is required.

The security of commerce depending, in good measure, on the justness of weights, which are usually of lead, iron, or brass, most nations have taken care to prevent the falsification thereof, by stamping or marking them by proper officers, after being adjusted by some original standard. Thus, in England, the standard of weights is kept in the exchequer by a particular officer, called the *clerk of the market*.

Weights may be distinguished into ancient and modern, foreign and domestic.

Ancient WEIGHTS, 1. Those of the ancient Jews, reduced to the English Troy weights, will stand as in the following table:

| | | lb. | oz. | dwt. | gr. |
|--------|-----------|-----|-----|------|-------------------|
| Shekel | - | - | 0 | 0 | 9 $\frac{2}{3}$ |
| 60 | Manch | - | 2 | 3 | 6 $\frac{10}{12}$ |
| 3000 | 50 Talent | - | 113 | 10 | 1 $\frac{10}{12}$ |

2. Grecian and Roman weights, reduced to English Troy weight; will stand as in the following table:

| | | | | oz. | dwt. | gr. |
|--------|-----------------------------------------|---------------------------|---|-----|------|------------------|
| Lentes | - | - | - | 0 | 0 | 0 $\frac{1}{12}$ |
| 4 | Siliquæ | - | - | 0 | 0 | 3 $\frac{1}{8}$ |
| 12 | 3 Obolus | - | - | 0 | 0 | 9 $\frac{1}{8}$ |
| 24 | 6 2 | Scriptulum | - | 0 | 0 | 18 $\frac{1}{4}$ |
| 72 | 18 6 3 | Drachma | - | 0 | 2 | 6 $\frac{1}{2}$ |
| 96 | 24 8 4 | 1 $\frac{1}{2}$ Sextula | - | 0 | 3 | 0 $\frac{6}{16}$ |
| 144 | 36 12 6 2 | 1 $\frac{1}{2}$ Sicilicus | - | 0 | 4 | 13 $\frac{3}{4}$ |
| 192 | 48 16 8 2 $\frac{1}{2}$ 1 $\frac{1}{2}$ | Ducella | - | 0 | 6 | 1 $\frac{1}{2}$ |
| 576 | 144 48 24 8 6 4 3 | Uncia | - | 0 | 18 | 5 $\frac{1}{2}$ |
| 6912 | 1728 576 288 96 72 48 36 12 | Libra | - | 10 | 18 | 13 $\frac{1}{2}$ |

The Roman ounce is the English averdupois ounce, which they divided into 7 denarii, as well as 8 drachms; and since they reckoned their denarius equal to the Attic drachm, this will make the Attic weights one eighth heavier than the corresponding Roman weights.

Modern European WEIGHTS. 1. English weights: by the 27th chapter of *magna carta*, the weights all over England are to be the same; but for different commodities there are two different sorts, viz. Troy weight and averdupois weight. The origin from which they are both raised, is a grain of wheat gathered in the middle of the ear.

In Troy weight, 24 of these grains make a penny-weight sterling; 20 penny-weights make 1 ounce; and 12 ounces 1 pound. See **TROY**.

By this weight we weigh gold, silver, jewels, grains, and liquors. The apothecaries also use the Troy pound, ounce,

Weight. ounce, and grain; but they differ from the rest in the intermediate divisions. They divide the ounce into 8 drachms, the drachm into 3 scruples, and the scruple into 28 grains. See ARITHMETIC, p. 655.

In averduois weight, the pound contains 16 ounces, but the ounce is less by near one-twelfth than the Troy ounce; this latter containing 490 grains, and the former only 448. The ounce contains 16 drachms. Eighty ounces averduois are only equal to 73 ounces Troy; and 17 pounds Troy equal to 14 pounds averduois. See AVERDUOIS.

By this weight are weighed mercury and grocery wares, base metals, wool, tallow, hemp, drugs, bread, &c. See ARITHMETIC, p. 655.

The moneyers, jewellers, &c. have a particular class of weights for gold and precious stones, viz. carat and grain; and for silver, the penny-weight and grain. See the article CARACT.

The moneyers have also a peculiar subdivision of the grain Troy: Thus,

| | | | | | |
|-----|---|-------|------|----|---------|
| The | { | Grain | into | 20 | Mites. |
| | | | | 24 | Droits. |
| | | | | 20 | Perits. |
| | | | | 24 | Blanks. |

The dealers in wool have likewise a particular set of weights, viz. the sack, weigh, tod, stone, and clove.

2. French weights: The common or Paris pound is 16 ounces; which they divide two ways: the first division is into 2 marcs; the marc into 8 ounces; the ounce into 8 gros; the gros into 3 penny-weights; the penny-weight into 24 grains; the grain equivalent to a grain of wheat. The second division of the pound is into 2 half-pounds; the half-pound into 2 quarters; the quarter into 2 half-quarters; the half-quarter into 2 ounces; and the ounce into 2 half-ounces.

The weights of the first division are used to weigh gold, silver, and the richer commodities; and the weights of the second division for commodities of less value.

Grains.

| | | | | |
|------|---------------|-------|--------|--------|
| 24 | Penny-weight. | | | |
| 72 | 3 | Gros. | | |
| 576 | 24 | 8 | Ounce. | |
| 4608 | 192 | 64 | 8 | Marc. |
| 9216 | 384 | 128 | 16 | Pound. |

Half-ounce.

| | | | | | |
|------|--------|--------------------|----------------|-------------|----------|
| 2 | Ounce. | | | | |
| 4 | 2 | Half-quarter pound | | | |
| 8 | 4 | 2 | Quarter-pound. | | |
| 16 | 8 | 4 | 2 | Half-pound. | |
| 32 | 16 | 8 | 4 | Pound. | |
| 3200 | 1600 | 800 | 400 | 100 | Quintal. |

But the pound is not the same throughout France.

At Lyons, *e. gr.* the city pound is only 14 ounces: so that 100 Lyons pounds make only 88 Paris pounds. But beside the city pound, they have another at Lyons for silk, containing 16 ounces. At Tholouse, and throughout the Upper Languedoc, the pound is 13 ounces and a half of Paris weight. At Marseilles, and throughout Provence, the pound is 13 ounces of Paris weight. At Rouen, beside the common Paris pound and marc, they have the weight of the vicomte; which is 16 ounces, a half, and five-sixths of the Paris weight. The weights enumerated under the two articles of English and French weights, are the same that are used throughout the greatest part of Europe; only under somewhat different names, divisions, and proportions.

Particular nations have also certain weights peculiar to themselves: thus; Spain has its arrobas, containing 25 Spanish pounds, or one-fourth of the common quintal; its quintal macho, containing 150 pounds, or one-half common quintal, or 6 arrobas; its aldarne, containing one-sixteenth of its ounce. And for gold, it has its castellan, or one-hundredth of a pound. Its tomin, containing 12 grains, or one-eighth of a castilian. The same are in use in the Spanish West Indies.

Portugal has also its arroba, containing 32 Lisbon arratels, or pounds: Savary also mentions its faratelle, containing 2 Lisbon pounds; and its rottoli, containing about 12 pounds. And for gold, its chego, containing 4 carats. The same are used in the Portuguese East Indies.

Italy, and particularly Venice, have their migliaro, containing 4 mirres; the mirre containing 30 Venice pounds: the faggio, containing a sixth part of an ounce. Genoa has five kinds of weights, viz. large weights, whereby all merchandises are weighed at the custom-house; cash weights, for piasres and other species; the cantara, or quintal, for the coarsest commodities; the large balance for raw silks; and the small balance for the finer commodities. Sicily has its rottola, 32 and a half pounds of Messina.

Germany, Flanders, Holland, the Hanse towns, Sweden, Denmark, Poland, &c. have their schippont, which at Antwerp and Hamburg, is 300 pounds; at Lubeck, 320; and at Coningberg, 400 pounds. In Sweden, the schippont for copper is 320 pounds; and the schippont for provisions 400 pounds. At Riga and Revel, the schippont is 400 pounds; at Dantzic, 340 pounds; in Norway, 300 pounds; at Amsterdam, 300; containing 20 lyspondts, each weighing 15 pounds.

In Muscovy, they weigh their large commodities by the bercheroff, or berkewits, containing 400 of their pounds. They have also the poet, or poede, containing 40 pounds, or one-tenth of the bercheroff.

In order to show the proportion of the several weights used throughout Europe, we shall add a reduction of them to one standard, viz. the London and Amsterdam pound.

I. Proportion of the weights of the principal places of Europe.

The 100 lb. of England, Scotland, and Ireland are equal to

| | |
|----|----------------------------|
| 1b | oz. |
| 91 | 8 of Amsterdam, Paris, &c. |
| 96 | 8 of Antwerp or Brabant. |

Weights.

| lb | oz. |
|-----|-------------------------------------|
| 88 | 0 of Rouen, the viscounty weight. |
| 106 | 0 of Lyons, the city weight. |
| 90 | 9 of Rochelle. |
| 107 | 11 of Tholouse and Upper Languedoc. |
| 113 | 0 of Marseilles or Provence. |
| 81 | 7 of Geneva. |
| 93 | 5 of Hamburg. |
| 89 | 7 of Francfort, &c. |
| 96 | 1 of Leipzig, &c. |
| 137 | 4 of Genoa. |
| 132 | 11 of Leghorn. |
| 153 | 11 of Milan. |
| 152 | 0 of Venice. |
| 154 | 10 of Naples. |
| 97 | 0 of Seville, Cadiz, &c. |
| 104 | 13 of Portugal. |
| 96 | 5 of Leige. |
| 112 | $\frac{1}{2}$ of Russia. |
| 107 | $\frac{1}{2}$ of Sweden. |
| 89 | $\frac{1}{2}$ of Denmark. |

II. Proportion of the weights of the chief cities in Europe to those of Amsterdam.

An 100 pounds of Amsterdam are equal to

| lb | |
|-------------------|----------------------------|
| 108 | of Alicant. |
| 105 | of Antwerp. |
| 120 | of Archangel, or 3 poedes. |
| 105 | of Arschor. |
| 120 | of Avignon. |
| 98 | of Basil in Switzerland. |
| 100 | of Bayonne in France. |
| 166 | of Bergamo. |
| 97 | of Bergen-op-zoom. |
| 95 $\frac{1}{2}$ | of Bergen in Norway. |
| 111 | of Bern. |
| 100 | of Befançon. |
| 100 | of Bilbao. |
| 105 | of Bois-le-duc. |
| 151 | of Bologna. |
| 100 | of Bourdeaux. |
| 104 | of Bourg en Bresse. |
| 103 | of Bremen. |
| 125 | of Breslaw. |
| 105 | of Bruges. |
| 105 | of Brussels. |
| 105 | of Cadiz. |
| 105 | of Cologne. |
| 125 | of Coningsberg. |
| 107 $\frac{1}{2}$ | of Copenhagen. |
| 87 | rotto of Constantinople. |
| 113 $\frac{1}{2}$ | of Dantzic. |
| 100 | of Dort. |
| 97 | of Dublin. |
| 97 | of Edinburgh. |
| 143 | of Florence. |
| 98 | Francfort on the Maine. |
| 105 | of Gaunt. |
| 89 | of Geneva. |
| 163 | of Genoa, cash weight. |
| 102 | of Hamburg. |
| 106 | of Leyden. |
| 105 | of Leipzig. |
| 105 $\frac{1}{2}$ | of Liege. |
| 114 | of Lule. |

Weights

| lb | |
|-------------------|---------------------------------------|
| 143 | of Leghorn. |
| 106 $\frac{1}{2}$ | of Lisbon. |
| 109 | of London, averdupois weight. |
| 105 | of Lovane. |
| 105 | of Lubec. |
| 141 $\frac{1}{2}$ | of Lucca, light weight. |
| 116 | of Lyons, city weight. |
| 114 | of Madrid. |
| 105 | of Marlines. |
| 123 $\frac{1}{2}$ | of Marseilles. |
| 154 | of M ^a fina, light weight. |
| 168 | of Milan. |
| 120 | of Montpelier. |
| 125 | bercheroots of Muscovy. |
| 100 | of Nantes. |
| 106 | of Nancy. |
| 169 | of Naples. |
| 98 | of Nuremberg. |
| 100 | of Paris. |
| 112 $\frac{1}{2}$ | of Revel. |
| 109 | of Riga. |
| 100 | of Rochelle. |
| 146 | of Rome. |
| 100 | of Rotterdam. |
| 96 | of Rouen, viscounty weight. |
| 100 | of St Malo. |
| 100 | of St Sebastian. |
| 158 $\frac{1}{2}$ | of Saragosa. |
| 106 | of Seville. |
| 114 | of Smyrna. |
| 110 | of Stetin. |
| 81 | of Tholouse and Upper Languedoc. |
| 151 | of Turin. |
| 158 $\frac{1}{2}$ | of Valencia. |
| 182 | of Venice, small weight. |

WEIGHTS used in the several parts of Asia, the East Indies, China, Persia, &c. In Turkey, at Smyrna, &c. they use the batman, or battemant, containing six octos; the octo weighing 3 pounds four-fifths English. They have another batman much less, confisting, as the former, of six octos; but the octo only containing 15 ounces English: 44 octos of the first kind make the Turkish quintal. At Cairo, Alexandretta, Aleppo, and Alexandria, they use the rotto, rotton, or rottoli. The rottoli at Cairo, and other parts of Egypt, is 144 drachms; being somewhat over an English pound. At Aleppo there are three sorts of rottos: the first 720 drachms, making about 7 pounds English, and serving to weigh cottons, galls, and other large commodities; the second is 624 drachms, used for all silks but white ones, which are weighed by the third rotto of 700 drachms. At Seyda the rotto is 600 drachms.

The other ports of the Levant not named here, use some of these weights; particularly the occa, or occua, the rottoli, and rotto.

The Chinese weights are the piece, for large commodities; it is divided into 100 catis, or cattis; tho' some say into 125; the cati into 16 taels, or tales; each tael equivalent to 1 $\frac{1}{4}$ of an ounce English, or the weight of 1 rial and $\frac{1}{2}$, and containing 12 mas, or masses, and each mas 10 condrens. So that the Chinese piece amounts to 137 pounds English averdupois, and the cati to 1 pound 8 ounces. The picol for silk

con-

light. containing 66 catis and $\frac{1}{2}$; the bahar, bakaire, or barr, containing 300 catis.

Tonquin has also the same weights, measures, &c. as China. Japan has only one weight, viz. the cati; which however is different from that of China, as containing 20 taels. At Surat, Agra, and throughout the states of the Great Mogul, they use the man, or maund, whereof they have two kinds; the king's man, or king's weight; and the man simply; the first used for the weighing of common provisions, containing 40 seers, or ferres; and each seer a just Paris pound. The common man, used in the weighing of merchandise, consists likewise of 40 seers, but each seer is only estimated at 12 Paris ounces, or $\frac{1}{2}$ of the other seer.

The man may be looked on as the common weight of the East Indies, though under some difference of name, or rather of pronunciation; it being called *nao* at Cambaya, and in other places *mein*, and *maun*. The seer is properly the Indian pound, and of universal use; the like may be said of the bahar, tael, and cati, above-mentioned.

The weights of Siam, are the piece, containing two shans or cattis; but the Siamese cati is only half the Japonese, the latter containing 20 taels, and the former only 10; though some make the Chinese cati only 16 taels, and the Siamese 8. The tael contains 4 baats or ticals, each about a Paris ounce; the baat 4 felings or mayons; the mayon 2 fouangs; the fouang 4 payes; the paye 2 clams; the fompaye half a fouang.

It is to be observed, that those are the names of their coins as well as weights; silver and gold being commodities there sold, as other things, by their weights.

In the isle of Java, and particularly at Bantam, they use the gantan, which amounts to near 3 Dutch pounds. In Golconda, at Visapour, and Goa, they have the furatelle, containing 1 pound 14 ounces English; the mangalis, or mangelin, for weighing diamonds and precious stones, weighing at Goa 5 grains, at Golconda, &c. $5\frac{1}{2}$ grains. They have also the rotolo, containing $14\frac{1}{2}$ ounces English; the metrical, containing the sixth part of an ounce; the wall for piastras and ducats, containing the $73d$ part of a rial.

In Persia they use two kinds of batmans or mans; the one called *cabi* or *cheray*, which is the king's weight, and the other *batman* of *Tauris*. The first weighs 13 pounds 10 ounces English; the second $6\frac{1}{2}$ pounds. Its divisions are the ratel, or a 16th; the derhem, or drachm, which is the 50th; the melschal, which is half the derhem; the dung, which is the 6th part of the melschal, being equivalent to 6 carat-grains; and, lastly, the grain, which is the fourth part of the dung. They have also the vakie, which exceeds a little our ounce; the sah-cheray, equal to the 1170th part of the derhem; and the toman, used to weigh out large payments of money without telling; its weight is that of 50 abassis.

African and American WEIGHTS. We have little to say as to the weights of America: the several European colonies there making use of the weights of the states or kingdoms of Europe they belong to. For as to the aroue of Peru, which weighs 27 pounds, it is evidently no other than the Spanish arroba with a little difference in the name.

As to the weights of Africa, there are few places

that have any, except Egypt, and the countries bordering on the Mediterranean; whose weights have been already enumerated among those of the ports of the Levant. The island of Madagascar indeed has weights, but none that exceed the drachm; nor are they used for any thing but gold and silver.

Regulation of WEIGHTS and Measures, is a branch of the king's prerogative. See PREROGATIVE, (and MEASURES in the APPENDIX.)

These, for the advantage of the public, ought to be universally the same throughout the kingdom; being the general criterions which reduce all things to the same or an equivalent value. But as weight and measure are things in their nature arbitrary and uncertain, it is therefore expedient that they be reduced to some fixed rule or standard: which standard it is impossible to fix by any written law or oral proclamation; for no man can, by words only, give another an adequate idea of a foot-rule, or a pound weight. It is therefore necessary to have recourse to some visible, palpable, material standard; by forming a comparison with which, all weights and measures may be reduced to one uniform size; and the prerogative of fixing this standard, our ancient law vested in the crown, as in Normandy it belonged to the duke. This standard was originally kept at Winchester: and we find in the laws of king Edgar, near a century before the conquest, an injunction that the one measure, which was kept at Winchester, should be observed throughout the realm. Most nations have regulated the standard of measures of length by comparison with the parts of the human body; as the palm, the hand, the span, the foot, the cubit, the ell (*ulna* or arm), the pace, and the fathom. But as these are of different dimensions in men of different proportions, our ancient historians inform us, that a new standard of longitudinal measure was ascertained by king Henry the First; who commanded that the *ulna* or ancient ell, which answers to the modern yard, should be made of the exact length of his own arm. And one standard of measures of length being gained, all others are easily derived from thence; those of greater length by multiplying, those of less by dividing, that original standard. Thus, by the statute called *compositio ulnarum et perticarum*, five yards and an half make a perch; and the yard is subdivided into three feet, and each foot into 12 inches; which inches will be each of the length of three grains of barley. Superficial measures are derived by squaring those of length; and measures of capacity by cubing them. The standard of weights was originally taken from corns of wheat, whence the lowest denomination of weights we have is still called a *grain*; 32 of which are directed, by the statute called *compositio mensurarum*, to compose a penny-weight, whereof 20 make an ounce, 12 ounces a pound, and so upwards. And upon these principles the first standards were made; which, being originally so fixed by the crown, their subsequent regulations have been generally made by the king in parliament. Thus, under king Richard I. in his parliament holden at Westminster, A. D. 1197, it was ordained that there should be only one weight and one measure throughout the kingdom, and that the custody of the office or standard of weights and measures should be committed to certain persons in every city and borough; from whence the ancient

Weight.

Weight. office of the king's aulnager seems to have been derived; whose duty it was, for a certain fee, to measure all cloths made for sale, till the office was abolished by the statute 11th and 12th William III. c. 20. In king John's time this ordinance of king Richard was frequently dispensed with for money; which occasioned a provision to be made for enforcing it, in the great charters of king John and his son. These original standards were called *pondus regis*, and *mensura domini regis*, and are directed by a variety of subsequent statutes to be kept in the exchequer chamber, by an officer called the *clerk of the market*, except the wine gallon, which is committed to the city of London, and kept in Guildhall.

The *Scottish* standards are distributed among the oldest boroughs. The elwand is kept at Edinburgh, the pint at Stirling, the pound at Lanark, and the first at Linlithgow.

Various statutes have been enacted for regulating and enforcing an uniformity of weights and measures; and by the articles of union, the English standards are established by law over all Great Britain. But the force of custom is so strong, that these statutes have been ill observed. The *Scottish* standards are still universally retained for many purposes; and likewise a variety of local weights and measures are used in particular places of both countries, which differ from the general standards of either.

1. *English Troy WEIGHT* is the most ancient of the different kinds used in Britain. See the article *Troy*. See also *ARITHMETIC*, p. 655, Tab. III. IV. the former exhibiting the divisions used by goldsmiths, the latter those used by apothecaries.—Goldsmiths in Scotland sometimes divide the ounce into 16 drops, and the drop into 30 grains; but in all these ways the ounce and grain is the same, and the ounce contains 480 grains.

A carat is a weight of 4 grains; but when the term is applied to gold, it denotes the degree of fineness. Any quantity of gold is supposed divided into 24 parts. If the whole mass be pure gold, it is said to be 24 carats fine; if there be 23 parts of pure gold, and 1 part of base metal or alloy, it is said to be 23 carats fine, and so on.

Pure gold is too soft to be used for coin. The standard coin of this kingdom is 22 carats fine. A pound of standard gold is coined into 44½ guineas, and therefore every guinea should weigh 5 dwts. 9½ grains; but as some allowance must be made for wearing, guineas not under 5 dwts. 8 gr. and half guineas not under 2 dwts. 16 gr. cannot be refused in payment.

A Joannes should weigh 9 dwts. 6 gr. Other Portugal pieces in proportion.

A pound of standard silver for coin contains 11 ounces 2 dwts. pure silver, and 18 dwts. alloy: standard silver-plate, 11 ounces pure silver, and 1 ounce alloy. A pound of silver is coined into 62 shillings; therefore the weight of a shilling should be 3 dwts. 20½ grains.

The value of a pound of gold, when coined at the mint-price, is L. 46 : 14 : 6, and the value of a pound of silver L. 3. 2s.; but the current price of bullion varies like that of other commodities, according to the scarcity or demand.

About the time of the Norman conquest, 1 lb. of Silver was coined into 20 shillings, and made L. 1 of

the current money of the realm. The value of the coin was afterwards lessened by degrees; and at present a pound sterling in silver does not contain one third part of that quantity. The sums of money mentioned in the earlier part of the English history, must be understood according to the state of the coin which was current at the time. They may be reduced to money of our present standard by the help of the following table; which exhibits the number of shillings coined from 1 lb. of silver, and the value of 20 of these shillings in our present money.

| Years. | Reigns. | Shill. coined from 1 lb. | Value of 20s. |
|--------|-------------|--------------------------|---------------|
| 1066 | Will. I. | 21 s 4 d | L. 2 18 1½ |
| 1087 | Will. II. | 20 s | 3 2 — |
| 1300 | Edward I. | 20 s 3 d | 3 1 2½ |
| 1305 | Richard II. | 25 s | 2 9 7½ |
| 1412 | Henry IV. | 32 s | 1 18 9 |
| 1422 | Henry V. | 37 s 6 d | 1 13 ¼ |
| 1426 | Henry VI. | 30 s | 2 1 4 |
| 1461 | Edward IV. | 37 s 6 d | 1 13 ¼ |
| 1505 | Henry VII. | 40 s | 1 11 — |
| 1509 | Henry VIII. | 45 s | 1 7 6½ |
| 1543 | Ditto | 48 s | 1 3 3½ |
| 1560 | Elizabeth | 60 s | 1 — 8 |
| 1601 | Ditto | 62 s | 1 — — |

This table will enable the reader to compare the old prices of provisions and other commodities with the present. He will find that the prices of corn about the time of the Norman conquest was only about one tenth of the present price, and cattle were still cheaper in proportion.

It appears, by a household-book composed by the earl of Northumberland in the year 1512, that wheat was about 6s. 2 d. per quarter, malt 4s. oats 2s. a lean ox 8s. a fat ox 13s. 4d. a sheep 1s. 8d. a hog 2s. a hen 2d. a goose 3d. French wine L. 4 : 13 : 4 per ton, an ell of linen 8d. a chaldre of coals 4s. 2 d. The weight of the coin was then one third more than at present.

The prices of commodities increased slowly before the discovery of America. In the 16th century, when great quantities of gold and silver were brought from the Spanish colonies in America, the value of these metals diminished of course, and prices rose quickly, and have since continued to increase. The price of corn was formerly much more unequal than at present. A scarcity in any particular country had worse effects, because commerce was not so regular. During a dearth in Queen Elizabeth's time, wheat rose to upwards of L. 4 per quarter.

2. *Averdupois WEIGHT* was afterwards brought into England. It owed its introduction to the practice of foreign merchants, but was afterwards established by law, and is now generally known by the name of *English weight*. The denominations used in this weight are contained in Table II. (*ARITHMETIC*, p. 655.) and are better adapted for bulky commodities, as those of *Troy* weight are for minute and valuable ones. The pound *avverdupois* contains 7000 grains *Troy*. The ounce was formerly divided into eight drachms, and the drachm into three scruples; but the present division of the ounce is into sixteen drops or drachms.

This weight is used in Scotland in collecting the revenue, and in selling leather, tallow, soap, flour, bread,

bread, candle, groceries, rosin, wax, pitch, wrought metals, some Baltic goods, and all goods brought from England. It is appointed by the articles of Union as the general weight through Great Britain; but has not been adopted in Scotland, except for the above mentioned commodities.

The following table is used for wool weight :

| | |
|-------------------------------------------------|-------------------|
| 7 lb = clove | 6½ tods = 1 wey |
| 2 cloves = 1 stone | 2 weys = 1 sack |
| 2 stones = 1 tod | 12 sacks = 1 last |
| 56 lb. old hay, or 60 lb. new hay, make a truss | |
| 36 trusses make a load | |
| 19½ cwt. lead make a fodder | |
| 14 lb. make a stone, horseman's weight | |
| 5 lb. glass a stone | |
| 14 oz. butcher-meat, in most places, make 1 lb. | |

3. *Trene* WEIGHT. See *TRONE*.

WEIMAR, a town of Upper Saxony, and in the territory of Thuringia, with a magnificent castle, wherein the duke resides. It is seated on the river Ilm, 20 miles north-east of Erfurt, and ten west of Jena. It is the capital of the duchy of Sax-Weimar. E. Long. 11. 18. N. Lat. 50. 10.

WELBY (Henry), a singular gentleman, was a native of Lincolnshire, where he had an estate of above 1000 pounds a year. He possessed, in an eminent degree, the qualifications of a gentleman. Having been a competent time at the university and the Inns of Court, he completed his education by making the tour of Europe. He was happy in the love and esteem of his friends, and indeed of all that knew him, as his heart was warm, and the virtues of it were conspicuous from his many acts of humanity, benevolence, and charity. When he was about 40 years of age, his brother, an abandoned profligate, made an attempt upon his life with a pistol; which not going off, he wrested it from his hands, and found it charged with a double bullet. Hence he formed a resolution of retiring from the world; and taking a house in Grubstreet, he reserved three rooms for himself; the first for his diet, the second for his lodging, and the third for his study. In these he kept himself so closely retired, that for 44 years he was never seen by any human creature, except an old maid that attended him, who had only been permitted to see him in some cases of great necessity. His diet was constantly bread, water-gruel, milk, and vegetables, and when he indulged himself most, the yolk of an egg. He bought all the new books that were published; most of which, upon a slight examination, he rejected. His time was regularly spent in reading, meditation, and prayer. No Carthusian monk was ever more constant and rigid in his abstinence. His plain garb, his long and silver beard, his mortified and venerable aspect, bespoke him an ancient inhabitant of the desert, rather than a gentleman of fortune in a populous city. He expended a great part of his income in acts of charity, and was very inquisitive after proper objects. He died the 29th of October 1636, in the 84th year of his age, and lies buried in St Giles's church, near Cripplegate. The old maid-servant died but six days before her master. He had a very amiable daughter, who married Sir Christopher Hilliard, a gentleman of Yorkshire; but neither she, nor any of her family, ever saw her father after his retirement.

WELD, or **WOLD**, in botany. See **RESEDA**.

WELDING-HEAT in smithery, a degree of heat given to iron, &c. sufficient only for bending or doubling it up.

Welding
||
Weld.

WELL, a hole under ground, usually of a cylindrical figure, and walled with stone and mortar: its use is to collect the water of the strata around it.

WELL, an apartment formed in the middle of a ship's hold to inclose the pumps, from the bottom to the lower deck. It is used as a barrier to preserve those machines from being damaged by the friction or compression of the materials contained in the hold, and particularly to prevent the entrance of ballast, &c. by which the tubes would presently be choked, and the pumps rendered incapable of service. By means of this inclosure, the artificers may likewise more readily descend into the hold, in order to examine the state of the pumps, and repair them, as occasion requires.

WELL of a *Fishing vessel*, an apartment in the middle of the hold, which is entirely detached from the rest, being lined with lead on every side, and having the bottom thereof penetrated with a competent number of small holes, passing also through the ship's floor; so that the salt-water running into the well is always kept as fresh as that in the sea, and yet prevented from communicating itself to the other parts of the hold.

WELL-room of a *Boat*, the place in the bottom where the water lies, between the ceiling and the platform of the stern-sheets, from whence it is thrown out into the sea with a scoop.

Burning-WELL. See **BURNING** WELL.

WELLS, a city of Somersetshire, and see of a bishop; the bishop of Bath being also that of Wells. —It is supposed to take its name from the many springs and wells that are near it. It is not very large; but is adorned with handsome buildings, both public and private. Its cathedral is a very beautiful structure, adorned with images and carved stone-work. The bishop's palace joins to the cathedral; and on the other side are the houses for the prebendaries. In the market-place is a fine market-house, supported by pillars. It is governed by a mayor, and sends two members to parliament. The chief manufacture is knit hose. W. Long. 2. 35. N. Lat. 51. 20.

WEN, a tumour or excrescence arising on different parts of the body, and containing a cythus or bag filled with some peculiar kind of matter. See **NÆVUS**.

WERGILD, the price of *homicide*; paid partly to the king for the loss of a subject, partly to the lord whose vassal he was, and partly to the next of kin of the person slain.

WEST (Gilbert), was the son of Dr West, prebendary of Winchester, and chaplain to king George I. but at 12 years of age lost his father. He studied at Winchester and Eton schools, and from thence was placed in Christ-church college, Oxford. His studious and serious turn inclined him to take orders; but lord Cobham, his uncle, diverted him from that pursuit, and gave him a cornetcy in his own regiment. This profession he soon quitted, on account of an opening of another nature, which presented him a flattering prospect of advancement in life. A number of young gentlemen were to be elected from the universities, and, at the expense of the government, were to be taught foreign languages, and then sent to the secretaries office, to be initiated into

business,

West,
Westmin-
ster.

business, and trained there for public services, as envoys, ambassadors, &c. Mr Gilbert West was one of the few pitched upon; and on his first introduction into that office, lord Townsend, secretary of state, treated him with singular marks of regard, and the strongest inclinations to serve him were testified from all quarters. But his uncle lord Cobham's strong opposition to the measures of the government, rendered these advantages entirely fruitless; and the ministers honestly told Mr West, that he must not expect them to distinguish his merit, as any favours conferred upon him would be imputed as done to his uncle lord Cobham. Mr West now left that office, and all his views of making his fortune; and entering into marriage, retired to Wickam in Kent, where he lived in great domestic comfort and tranquil happiness. He was there visited by his valuable friends, who held the most delightful converse of wit, humour, and learning, supported upon the principles of virtue, sound reasoning, and solid friendship, which rendered the whole cheerful, animating, and instructive. Mr William Pitt, who was one of those that composed this happy society, becoming paymaster, appointed Mr West treasurer to Chelsea-hospital; and he obtained a seat at the council-board, in consequence of a friendship contracted at school with one of the duke of Devonshire's sons, who procured for his grace his being nominated one of the clerks extraordinary of that office. Towards the latter part of Mr West's life, he wholly applied himself to the study of the scriptures, being extremely anxious to try his utmost endeavours to reconcile the seeming inconsistencies which gave the enemies to revealed religion a handle to doubt and discredit their authenticity. His works bear testimony to his worth and learning. He had a mind replete with virtue, and was an honour to his country; but died at 50 years of age.

WEST, one of the cardinal points of the horizon, diametrically opposite to the east; and strictly defined the intersection of the prime vertical with the horizon on that side the sun sets in.

WESTMINSTER, a city which forms the west part of the capital of Britain, but has a government distinct from the rest. This city had its name from the situation of its abbey, anciently called a *minster*, in respect of that of St Paul. That part properly called the city of Westminster, comprehending the parishes of St John and St Margaret, was once an island formed by the Thames, called *Thorney island*, from the thorns with which it was over-run; and the abbey that stood in it, Thorney-abbey. The liberties of Westminster contain the several parishes of St Martin in the Fields, St James's, St Anne, St Paul, Covent-garden, St Mary le Strand, St Clement, Danes, St George, Hanover-square, and the precinct of the Savoy. The government, both of the city and liberties, is under the jurisdiction of the dean and chapter of Westminster, in civil as well as ecclesiastical affairs; and their authority extends to the precinct of St Martin le Grand, by Newgate-street, and in some towns of Essex, that are exempted from the jurisdiction of the bishop of London and the archbishop of Canterbury; but the management of the civil part has, ever since the Reformation, been in the hands of laymen, elected from time to time, and confirmed by the dean

Westmo-
land

and chapter. The chief of these laymen are the high-steward, the deputy-steward, and the high-bailiff, who hold their offices for life. There are also 16 burgesses and their assistants, out of which are elected two head-burgesses, one for the city, and the other for the liberties. Another officer is the high-constable, who has all the other constables under his direction.

WESTMORELAND, a small inland county of England, bounded on the east by part of Yorkshire, and the bishopric of Durham; on the south by Lancashire; and on the west and north by Cumberland. It extends 30 miles in length, and 24 in breadth, comprehending 32 parishes, eight market towns, a considerable number of villages, about 7000 houses, and about 35000 inhabitants. It is divided into the two great baronies of Westmoreland and Kendal; the former belonging to the diocese of Carlisle, and the latter to the bishopric of Chester. It was of old inhabited by the Brigantes; it afterwards constituted part of the Northumbrian kingdom; and now gives title of earl to the noble family of Fane.

Westmoreland is one of the most mountainous countries in England, particularly the barony of Kendal, which abounds in hills and fells, moors and rocks, besides the great ridge of mountains that separate this province from Yorkshire. Among the mountains of this county, one of the most remarkable is called *Isan-parler*, extremely high and difficult of access, famous for being, as it were, scooped into divers caverns and labrinths, which seem to have been formed as retreats in times of trouble and calamity. The county produces plenty of wood, both on the mountains and plains.

The largest lake in England is the Winander-merc of this county, lying among the mountains on the borders of Cumberland, stretching ten miles in length, of a very considerable depth, having a rocky bottom, fludded with several verdant isles or holmes, and abounding with the delicate fish called *char*, which being potted and preserved, is sent in presents from hence to all parts of England. It is swelled by the small rivers Ruthey and Brathey, which fall into it, and by its communication with a chain of small lakes called *Gresmere*. The most considerable rivers of this county are the Eden, the Can, the Lone, and the Loder. The last hath given the name to the ancient family of Lowther.

The air of Westmoreland is keen and salubrious; but the climate is moist, consequently not very agreeable. The barony of Kendal is mountainous, therefore not so fit for tillage as for pasture: but the other part, properly called *Westmoreland*, is an open champaign country, which, if well cultivated, would be fruitful in both. Besides the water of the common fountains and rivers, which is pure, agreeable, and fit for all the usual purposes, this county affords some springs of peculiar qualities. In Betham-park, there is the dropping-well, in which moss, wood, and leaves are petrified. On the north side of Jeffery-mount there is a small spring called *Goudsike*, which continually throws up small spangles that glitter like silver. In the neighbourhood of Burrow, upon Stanemore, the inhabitants have discovered a chalybeate fountain.

In all probability, the mountains of Westmoreland are well stored with minerals, though no mines are worked in this county: yet here is plenty of coal for fuel.

Weltphalia
Wetstein,

WETSTEIN (John James), a very learned German divine, born at Basil in 1693. On his admission to the ministry, he maintained a thesis *de variis Novi Testamenti lectionibus*; in which he showed that the great variety of readings of the New Testament

The most remarkable places in Westmoreland are Appleby, Shap, Kirkby-Stephen, Orton, Ambleside,

Wetteravia afford no argument against the authenticity of the text. He had made these various readings the object of his attention; and travelled into foreign countries to examine all the MSS. he could come at. In 1730, he published *Prolegomena ad Novi Testamenti Græci editionem accuratissimam*, &c. Some divines dreading his unsettling the present text, procured a decree of the senate of Basil against his undertaking, and even got him prohibited from officiating in the ministry; on which he went to Amsterdam, where the remonstrants named him to succeed the famous Le Clerc, then superannuated, as professor of philosophy and history. At last he published his edition of the New Testament, in 2 vols. folio, 1752; in which he left the text as he found it, placing the various readings, with a critical commentary, underneath; subjoining two epistles of Clemens Romanus, till then unknown to the learned, but discovered by him in a Syriac MS. of the New Testament. He also published some small works; and is said to have been not only a universal scholar, but to abound in good and amiable qualities. He died at Amsterdam of a mortification in 1754.

WETTERAVIA, the southern division of the Landgrate of Hesse in Germany, lying along the northern bank of the river Maine, comprehending the counties of Hanau and Nassau.

WEXFORD, or **WEISFORD**, a county of Ireland, in the province of Munster, bounded by Wicklow on the north, St George's channel on the south and south-west, and part of Catherlogh and Kilkenny on the west. Its greatest length is about 47 miles, breadth about 27, and contains eight baronies. The air is good, but the soil various. In some places it is coarse and poor, in others fruitful both in corn and grass. The county sends 18 members to parliament; namely, two for the county, and two for each of the boroughs of Wexford, New-Ross, Ennecorothy, Feathard, Newborough, Bannow, Clomenis, Taghman.

WEXFORD, or *Weisford*, the capital of the above county, is a large ancient town, at the mouth of the Slane, the first place the English got possession of when they invaded Ireland in 1170, and is now much frequented by strangers in summer, on account of a chalybeate spring near it. Here is a very good harbour for vessels of considerable burden, and barracks for two companies of foot, with a very ancient castle still standing. Both Wexford and Waterford give title of earl to the Talbots, earls of Shrewsbury, in England.

WEYMOUTH, a town of Dorsetshire in England, deriving its name from its situation at the mouth of the river Wey. It is a very neat agreeable town, though it lies low. Melcombe-Regis, which stands on the opposite bank of the river, makes with it but one corporation, which sends as many members to parliament as London; every voter having, as in the capital, the privilege of polling for four persons. The corporation consists of a mayor, recorder, two bailiffs, 24 capital burgesses; and every mayor is an alderman for life. Here is a customhouse and good quay; but little trade, unless what is clandestine. Their fair trade is chiefly in wine, and fish brought from Newfoundland. The town gives title of viscount to the family of Thynne.—Melcombe-Regis, as we observed before, makes but one corporation with Weymouth, being situated upon the opposite bank of the river,

and joined to it by a bridge. These towns were united into one corporation in the reign of James I. Melcombe has four tolerable streets, and is the most thriving and populous of the two. The port, which is said to be the most frequented in the county, and is defended by two castles, goes by the name of *Weymouth*.

WHALE, in ichthyology. See *BALÆNA* and *PHYSETER*.

WHARF, a space on the banks of a haven, creek, or hithe, provided for the convenient loading and unloading of vessels.

WHARTON, (Philip duke of), a nobleman of the most brilliant parts, but of the most whimsical, extravagant, and inconsistent turn of mind, was educated by his father's express order at home. He very early married a young lady, the daughter of major-general Holmes, which disappointed his father's views of disposing of him in such a marriage as would have been a considerable addition to the fortune and grandeur of his illustrious family; yet that amiable lady deserved infinitely more felicity than she met with by this alliance. This precipitate marriage is thought to have hastened the death of his father; after which the duke being free from paternal restraints, plunged into those excesses which rendered him, as Pope expresses it,

"A tyrant to the wife his heart approv'd,"

"A rebel to the very king he loved."

In the beginning of the year 1716, his lordship began his travels; and as he was designed to be instructed in the strictest Whig principles, Geneva was thought a proper place for his residence. He first passed through Holland, and visited several courts of Germany; and being arrived at Geneva, conceived such a disgust against his governor, that he left him, and set out post for Lyons, where he wrote a letter to the chevalier de St George, who then resided at Avignon, and presented him a very fine stout horse; which the chevalier no sooner received than he sent a man of quality to him, who took him privately to his court, where he was entertained with the greatest marks of esteem, and had the title of duke of Northumberland conferred upon him. He, however, remained there but one day, and then returned post to Lyons, from whence he set out for Paris. He likewise paid a visit to the consort of James II. who then resided at St Germain, to whom he also paid his court. During his stay at Paris, his winning address and abilities gained him the esteem and admiration of all the British subjects of rank of both parties.

About the latter end of December 1716, he arrived in England, whence he soon after set out for Ireland, where, though under age, he was allowed the honour to take his seat in the house of peers, and immediately distinguished himself, notwithstanding his former conduct, as a violent partizan for the ministry; in consequence of which zeal the king created him a duke. He no sooner came of age than he was introduced to the house of lords in England with the same blaze of reputation. In a little time he opposed the court, and appeared one of the most vigorous in defence of the bishop of Rochester; and soon after printed his thoughts twice a-week, in a paper called the *True Briton*, several thousands of which were dispersed weekly.

The duke's boundless profusion had by this time

Whale
Wharton

so burdened his estate, that by a decree of Chancery it was vested in the hands of trustees for the payment of his debts, allowing him a provision of 1200l. per ann. for his subsistence. This being not sufficient to support his title with suitable dignity, he went abroad and thence to great advantage, with respect to his personal character, at the Imperial court. From thence he made a tour to Spain; where the English minister was so alarmed at his arrival, as to send two expresses from Madrid to London, upon the apprehension that his grace was received there in the character of an ambassador: upon which the duke received a summons under the privy-seal to return home; but instead of obeying it, he endeavoured to inflame the Spanish court against that of Great-Britain, for exercising an act of power, as he was pleased to call it, within the jurisdiction of his catholic majesty. He then acted openly in the service of the Pretender, and was received at his court with the greatest marks of favour.

While his grace was thus employed, his neglected duchess died in England on the 14th of April 1726, without issue; and soon after the duke fell violently in love with M. Oberne, one of the maids of honour to the queen of Spain, the daughter of an Irish colonel who had died in that service, and whose fortune chiefly consisted in her personal accomplishments. All his friends, and particularly the queen of Spain, opposed the match; but he falling into a lingering fever, occasioned by his disappointment, the queen gave her consent, and they were soon after married. He then spent some time at Rome, where he accepted of a blue garter, assumed the title of duke of Northumberland, and for a while enjoyed the confidence of the exiled prince. But not always keeping within the bounds of Italian gravity, it became necessary for him to remove from thence; when, going by sea to Barcelona, he wrote a letter to the king of Spain, acquainting him that he would assist at the siege of Gibraltar as a volunteer. The king thanked him for the honour, and accepted his service: but the duke soon growing weary, wrote a respectful letter to the chevalier de St George, expressing a desire to visit his court; but the chevalier advised him to draw near to England.

The duke seemed resolved to follow his advice; and setting out with his duchess, arrived at Paris in May 1728, whence he soon after proceeded to Rouen, where he took up his residence; and was so far from making any concession to the government of England, that he did not give himself the least trouble about his estate, or any other concern there; though, on his arrival at Rouen, he had only about 600l. in his possession, and a bill of indictment was preferred against him in England for high-treason. Soon after the chevalier sent him 2000l. which he squandered away in a course of extravagance; when, to save the charges of travelling by land, he went from Orleans to Nantz by water, and staid there till he got a remittance from Paris, which was squandered almost as soon as received. At Nantz he was joined by his ragged servants, and from thence took shipping with them for Bilbao, when the queen of Spain took the duchess to attend her person. About the beginning of the year 1731, the duke, who commanded a regiment, was at Lerida, but declined so fast that he could not move without assistance; yet when free from pain did not lose his gaiety. He,

however, received benefit from some mineral waters in Catalonia; but soon after relapsed at a small village, where he was utterly destitute of all the necessaries of life, till some charitable fathers of a Bernardine convent removed him to their house, and gave him all the relief in their power. Under their hospitable roof he languished a week, and then died, without one friend or acquaintance to close his eyes; and his funeral was performed in the same manner in which the fathers inter those of their own fraternity.

Thus died Philip duke of Wharton, "who, like Buckingham and Rochester (says Mr Walpole), comforted all the grave and dull, by throwing away the brightest profusion of parts on witty fooleries, debaucheries, and serapes, which may mix graces with a great character, but never can compose one. If Julius Cæsar had only rioted with Catiline, he had never been emperor of the world. Indeed, the duke of Wharton was not made for conquests; he was not equally formed for a round-house and Pharosia: in one of his ballads he bantered his own want of heroism. It was in a song he made on being seized by the guard in St James's park, for fingering the Jacobite air, The king shall have his own again.

The duke he drew out half his sword,
The guard drew out the rest.

"With attachment to no party, though with talents to govern any party, this lively man changed the free air of Westminster for the gloom of the Elicurial, the prospect of king George's garter for the Pretender's; and with indifference to all religion, the frolic lord who had writ the ballad on the archbishop of Canterbury, died in the habit of a capuchin. It is difficult to give an account of the works of so mercurial a man, whose library was a tavern, and women of pleasure his muses. A thousand fallacies of his imagination may have been lost. There are only two volumes in 8vo, called his *Life and Writings*. These contain nothing of the latter, but 74 numbers of the True Briton, and his speech against the bishop of Rochester. His other works are the ballads above mentioned; the Drinking Match at Eden-hall, in imitation of the Chevy-Chace, printed in a miscellany called *Whartoinana*; and a parody of a song sung at the opera-house by Mrs Tofts. His lordship also began a play on the story of the queen of Scots."

WHARTON (Henry), a learned English divine, was born in 1664, at Worstead in Norfolk, of which parish his father was vicar. He studied at Gonville and Caius college, Cambridge, where he prosecuted his studies with great vigour; and was instructed in the mathematics by Mr Isaac Newton, amongst a select company to whom that great man taught that science in his own private chamber. He afterwards assisted Dr William Cave in compiling his *Historia Literaria*, and at length became tutor to the only son of the Lord Arundel. In 1678, he distinguished himself by publishing several pieces in defence of the Protestant religion; and, though as yet no more than a deacon, was honoured by archbishop Sancroft with a licence for preaching through the whole province of Canterbury, and was also made one of the archbishop's chaplains. The same year he obtained the vicarage of Minister in the Isle of Thanet, and afterwards the rectory of Chatham; but died in the 31st year of his

Wharton.

Wheat
Wheelings.

Wheeling
Which.

age, in consequence of his immoderate studies. He was interred in Westminster abbey, where a small monument is erected to his memory. He was a man of great natural endowments; and was modest, sober, pious, and charitable. His death was greatly lamented by all learned men both at home and abroad. His principal works are, *Anglia Sacra*, 2 vols, folio; and *Historia de Episcopis et Decanis Londinensibus*, 8vo.

WHEAT, in botany. See TRITICUM. For the culture of wheat, see AGRICULTURE, n° 112—115.

WHEEL, in mechanics, a simple machine, consisting of a round piece of wood, metal, or other matter, which revolves on its axis. See MECHANICS.

WHEEL-Carriages. See MECHANICS, chap. v.

WHEEL-Animal. See ANIMALCULE, n° 16—22.

WHEEL of *Orffyreus*, a machine supposed by professor Gravefande to be a perpetual motion; of which we have the following account in a Letter from the Professor to Sir Isaac Newton. "It is an hollow wheel, or kind of drum, about 14 inches thick, and 12 feet diameter; being very light, as it consists of several croses pieces of wood framed together; the whole of which is covered over with canvas, to prevent the inside from being seen. Thro' the centre of this wheel or drum runs an axis of about 6 inches diameter, terminated at both ends by iron axes of $\frac{1}{4}$ ths of an inch diameter, upon which the machine turns. I have examined these axes, and am firmly persuaded that nothing from without the wheel in the least contributes to its motion. When I turned it but gently, it always stood still as soon as I took away my hand; but when I gave it any tolerable degree of velocity, I was always obliged to stop it again by force; for when I let it go, it acquired in two or three turns its greatest velocity, after which it revolved from 25 to 26 times in a minute. This motion it preserved some time ago for two months, in an apartment of the castle: the doors and windows of which were locked and sealed, so that there was no possibility of fraud. At the expiration of that term, indeed his serene highness ordered the apartment to be opened, and the machine to be stopped; least, as it was only a model, the parts might suffer by so much agitation. The landgrave being himself present on my examination of this machine, I took the liberty to ask him, as he had seen the inside of it, whether, after being in motion for a certain time, no alteration was made in the component parts; or whether none of those parts might be suspected of concealing some fraud; on which his serene highness assured me to the contrary, and that the machine was very simple."

WHEELER (Sir George), a learned traveller and divine, was the son of colonel Wheeler of Charing in Kent, and was born in 1650 at Breda, where his parents as royalists were then in exile. He travelled through various parts of Greece and the East in company with Dr James Spon of Lyons; and taking orders on his return, was installed a prebend of Durham, made vicar of Basingstoke, and afterward rector of Houghton le Spring. He published an account of his Travels in 1682 in folio; and in 1689, his Observations on ancient edifices of Churches yet remaining in the East, compared with Eusebius: also the Protestant Monastery, or Christian oeconomies. He died in 1724.

WHEELINGS, in the military art, are different motions made both by horse and foot, either to the

right and left, or to the right and left about.

General Rules for WHEELING. The circle is divided into four equal points: thence, wheeling to the right or left, is only a quarter of the circle; wheeling to the right or left about, is one half of the circle.

When you wheel to the right, you are to close to the right, so near as to touch your right-hand man, but without pressing him; and to look to the left, in order to bring the rank about even.

When you wheel to the left, you are to close to the left, and look to the right, as above directed. This rule will serve for all the wheeling by ranks; as when a battalion is marching by subdivisions with their ranks open, then each rank wheels distinctly by itself, when it comes to the ground on which the ranks before it wheeled, but not before.

In wheeling, the men are to take particular care neither to open nor close their ranks, and to carry their arms well.

In wheeling, the motion of each man is quicker or slower, according to the distance he is from the right or the left: thus, when you wheel to the right, each man moves quicker than his right-hand man; and wheeling to the left, each man moves quicker than his left-hand man; the circle that every man wheels being larger, according to the distance he is from the hand he wheels to; as may be seen by describing several circles within one another, at two feet distance from each, which is nearly the space every man is supposed to take up.

WHEELK, in zoology. See BUCCINUM.

WHELP, the young of a dog, fox, lion, or any wild beast.

WHELPS, in a ship, the seaman's term for those brackets which are set up on the capstan close under the bars; they give the sweep to it, and are so contrived that the cable winding about them may not surge so much as it might otherwise do if the body of the capstan were quite round and smooth.

WHETSTONE, a stone which serves for the whetting of knives and other tools upon.

WHEY, the serum, or watery part of milk.

WHICHCOT (Dr Benjamin), a learned English divine, was born in Shropshire in 1609, and educated at Cambridge, where he was chosen fellow of his college, and was an excellent tutor and instructor of youth. He was afterwards made provost of King's college, where he was a most vigilant and prudent governor, a great encourager of learning and good order, and by his wise management of the estate of the college he brought it into a very flourishing condition. After he left Cambridge he came to London, and was chosen minister of Blackfriars, where he continued till the fire of London, and then retired to a donative which he had at Milton near Cambridge, where he preached constantly, and relieved the poor. In 1668 he was presented to the rectory of St. Laurence Jewry; but during the building of that church, he preached for about the space of seven years before the court of aldermen at Guildhall chapel with great approbation. When his church was built, he constantly officiated twice a week, and gained the general love and respect of his parish. He died in 1683. Dr John Tillotson preached his funeral sermon, in which his character is drawn to great advantage. His Select Sermons were printed

Whig printed in London in 1698, with a preface by the late Earl of Shaftesbury author of the *Characteristicks*.

WHIG, a party in Britain, opposite to the Tories, from whom they differ chiefly in their political principles. See *TORIES*.

The names of *Whig* and *Tory* were not known till about the middle of the reign of Char. II. when these were given as party-distinctions. These parties may be considered either with regard to the state, or to religion. The state Tories are either violent or moderate: the first would have the king to be absolute; and therefore plead for passive obedience, non-resistance, and the hereditary right of the house of Stuart. The moderate Tories would not suffer the king to lose any of his prerogative; but then they would not sacrifice those of the people. The state Whigs are either strong republicans or moderate ones. "The first (says Rapin) are the remains of the party of the long parliament, who attempted to change monarchy to a commonwealth: but these make no slender a figure, that they only serve to strengthen the party of the other Whigs. The Tories would persuade the world, that all the Whigs are of this kind; as the Whigs would make us believe that all the Tories are violent. The moderate state Whigs are much in the same sentiments with the moderate Tories, and desire that the government may be maintained on the ancient foundation: all the difference is, that the first bear a little more to the parliament and people, and the latter to that of the king. In short, the old Whigs were always jealous of the encroachments of the royal prerogative, and watchful over the preservation of the liberties and properties of the people.

WHIP, or WHIP-Staff, in a ship, a piece of timber, in form of a strong staff, fastened into the helm, for the steersman, in small ships, to hold in his hand, in order to move the rudder and direct the ship.

WHIRLPOOL, an eddy, vortex, or gulph, where the water is continually turning round.

These in rivers are very common, from various accidents, and are usually very trivial, and of little consequence. In the sea they are more rare, but more dangerous. Sibbald has related the effects of a very remarkable marine whirlpool among the Orcades, which would prove very dangerous to strangers, though it is of no consequence to the people who are used to it. This is not fixed to any particular place, but appears in various parts of the limits of the sea among those islands. Wherever it appears, it is very furious; and boats, &c. would inevitably be drawn in and perished with it; but the people who navigate them are prepared for it, and always carry an empty vessel, a log of wood, or large bundle of straw, or some such thing, in the boat with them; as soon as they perceive the whirlpool, they toss this within its vortex, keeping themselves out: this substance, whatever it be, is immediately received into the centre, and carried under water; and as soon as this is done, the surface of the place where the whirlpool was becomes smooth, and they row over it with safety; and in about an hour they see the vortex begin again in some other place, usually at about a mile's distance from the first.

WHIRLWIND, a wind that rises suddenly, is exceedingly rapid and impetuous when risen, but is soon spent. See *WIND*.

VOL. X.

The origin of whirlwinds has been already given *Whirlwind.* under that of *WATER-SPOUT*. It is, however, highly probable that all these violent motions of the air are ultimately owing to the emission of electric matter from the earth. It is mentioned as a certain sign of an approaching hurricane in the West Indies, that the sea-water becomes exceedingly clear and transparent of a sudden; after which it seems to boil, and the waves begin to rise, though there is not the least wind. Both these phenomena can be accounted for on no other principle than that of a quantity of electric matter attempting to get out from the earth. Now though hurricanes are not precisely of the nature of whirlwinds, as not having a circular motion, it is highly probable that the latter also are occasioned somehow or other by a similar cause. A stream of electric matter issuing with violence into the atmosphere from any part of the earth, will cause a kind of vacuum in the atmosphere directly above that place, and of consequence a whirlwind or water-spout by the air rushing in on all sides to supply the vacuum*. If this is the true principle on which these phenomena depend, then we are sure that there never was any hurricane or whirlwind so violent as to remove an obstacle of the size of only one cubic inch, provided that was supported by a power equivalent to 15 pounds; for this is the utmost force of the atmosphere when rushing into a perfect vacuum, which never could take place in the centre of a whirlwind or water-spout. Indeed, notwithstanding the dreadful effects sometimes observed from hurricanes and whirlwinds, we shall easily perceive that the utmost of their power always falls very far short of this. The diminution of the specific gravity of the air by only $\frac{1}{4}$ th in the middle of the column, would produce such an afflux of air from all quarters, that an obstacle presenting a surface of one foot square would require a force of 504 pounds to prevent it from being carried away; which scarce the strongest walls that can be built by human art could resist. Nay, even the tenth part of this, or the diminution of the gravity of the atmosphere by $\frac{1}{10}$ th part, would produce a pressure of upwards of 50 pounds on every square foot of surface, which it is to be doubted whether any of our common houses could resist.

As this degree of rarefaction in the atmosphere would only produce a descent of about $\frac{1}{4}$ th of an inch in the barometer, it may seem wonderful why the most violent whirlwinds do not take place at those times when the mercury descends two or more inches, which descents are by no means unfrequent. But here it is to be remembered, that by whatever means this descent of the barometer is occasioned, by a certain expansive power in the rarefied place of the atmosphere, the air is prevented from rushing in eddies, and forming the whirlwind. Now, in the case of electric matter escaping from the earth, ascending into the high regions of the atmosphere, and carrying part of the air along with it, we see that there could be no expansion, but on the contrary a continued suction; and if the electric stream should happen to be stopped in one place and break out in another, the spout or whirlwind would immediately vanish in the one place and appear in the other, as is often observed in whirlwinds and water-spouts. Its progressive motion might be owing to the electric current perpetually shifting its place;

Whirlwind.
||
Whiston.

place; in which case the whirlwind would constantly follow it, for the reasons already given.

Some kinds of whirlwinds move with a slow motion, and are injurious only by their vortex; while others seem to do mischief as well by their progressive as their whirling motion. Of this kind are those called *typhons*; which, by their frequently following the course of rivers, seem thus also to discover their electrical origin. Of the destructive effects of these, we have an instance in what happened at Charlestown in South Carolina on the 1st of June 1761. It was first observed about noon, on land, upwards of 50 miles west-by-south of Charleston, and destroyed several houses, &c. as it passed along, in many places making wide avenues through the woods; from whence every tree and shrub was torn up, and great branches of trees were driven about in the column as it passed along. It directed its course to Ashley river, down which it came with surprising velocity; in its appearance resembling a column of smoke or vapour, whose motion was very irregular and tumultuous. Its momentum was so great, that Ashley river was ploughed to the bottom, and the channel laid bare. As it came down this river it made a constant noise like thunder; its diameter being computed about 300 fathoms. It was met at White Point by another of the same kind which came down Cooper's river, but with inferior strength; however, on their meeting together, the agitation of the air was much greater, while the clouds, which were driving in all directions to the place, seemed to be precipitated and whirled round with incredible velocity. It then fell upon the shipping in the road; entirely destroying some, and damaging others: being scarce three minutes in its passage, though the distance was near two leagues. In that short time it did damage to the amount of 20,000 l.; and had not its direction been altered by that gust which came down Cooper's river, it must have totally destroyed Charlestown, as no obstacle whatever seemed capable of resisting its fury.

It is observable, that whirlwinds do not arise with all their fury at once, but increase in strength as they go along. Dr Franklin relates, that he once rode for a considerable way by the side of one which had but newly arisen, and could scarce lift up any thing but dust, its vortex being only a few inches in diameter; but as it went along the strength and diameter constantly increased, till at last, as it began to take up and whirl round large branches of trees, it became dangerous for him to accompany it any longer. See *WATER-SPOUT and WIND*.

WHISPERING-PLACES. See *ACOUSTICS*, n°25.

WHIST, a well known game at cards, so called from the silence observed during the time of play.

WHISTON (William), an English divine of great parts, uncommon learning, and of a singular character, was born at Norton near Twycrosse in the county of Leicester, where his father was rector, in 1667. He was admitted of Clarehall, Cambridge, where he pursued his studies, particularly in the mathematics, and commenced tutor; which his ill health at length forced him to decline. Having entered into orders, he, in 1694, became chaplain to Dr More bishop of Norwich; and in this station he published his first work, intitled, *A New Theory of the Earth, &c.* in which he undertook to prove the Mosaic doctrine of the earth

perfectly agreeable to reason and philosophy: which work, though it was wrote against by Mr John Keil, brought no small reputation to the author. In the beginning of this century he was made Sir Isaac Newton's deputy, and afterward his successor, in the Lucasian professorship of mathematics; when he resigned a living he had in Suffolk, and went to reside at Cambridge. About this time he published several scientific works explanatory of the Newtonian philosophy; and he had the honour of being one of the first, if not the very first, who rendered those principles popular and intelligible to the generality of readers. About the year 1710, he was known to have adopted Arian principles, and was forming projects to support and propagate them: among other things, he had translated the Apostolical Constitutions into English, which favoured the Arian doctrine, and which he asserted to be genuine. The consequence was, that he was deprived of his professorship, and banished the university; he nevertheless pursued his scheme, by publishing the next year his *Primitive Christianity Revived*, 4 vols, 8vo. for which the convocation fell upon him very vehemently. On his expulsion from Cambridge Mr Whiston settled in London; where, without suffering his zeal to be intimidated, he continued to write, and to propagate his Primitive Christianity with as much ardour as if he had been in the most flourishing circumstances. In 1721, a subscription was made for the support of his family, which amounted to 470 l. For though he drew profits from reading astronomical and philosophical lectures, and also from his publications, which were very numerous, yet these of themselves would have been very insufficient: nor, when joined with the benevolence and charity of those who loved and esteemed him for his learning, integrity, and piety, did they prevent his being frequently in great distress. He continued long a member of the church of England, and regularly frequented its service, though he disapproved of many things in it: but at last he went over to the Baptists, and attended Dr Forster's meeting at Pinner's Hall, Broadstreet. Among other performances not specified above, he wrote *Memoirs of his own life and writings*, which contain some curious particulars. He died in 1762.

WHITBY (Dr Daniel), a very learned English writer, was born in 1638, and bred at Oxford; where in 1664 he was elected perpetual fellow of his college. He afterward became chaplain to Dr Seth Ward, bishop of Salisbury; who collated him in 1668 to the prebend of Yatebury in that church, and soon after to that of Hulsborn and Burbach. In 1672 he was admitted chanter of the said church on the death of Mr John South, and then, or soon after, rector of St Edmund's church in Salisbury. He was made a prebendary of Taunton Regis in 1696, and died in 1726. He was ever strangely ignorant of worldly affairs, even to a degree that is scarcely to be conceived. His writings are numerous, and well known; particularly his *Commentary on the New Testament*.

WHITBY, a sea-port town in the North Riding of Yorkshire, seated on the river Esk, near the place where it falls into the sea; over which there is a wooden bridge. It was formerly of great note for its abbey; which, though now in ruins, continues to be very useful as a land mark. The houses are neat, strong, and

Whito.

WHITE-Lead. See CHEMISTRY, n° 281.

WHITE-Throat, in ornithology. See MÔTACILLA.

WHITEFIELD (George), the celebrated preacher among the people called *Methodists*, was born in the year 1714, at the Bell in the city of Gloucester, which was then kept by his mother. At about 12 years of age he was put to a grammar school; but his mother entering into a second marriage, which proved a disadvantageous one, he, when about 15, put on a blue apron, and served her in the capacity of a drawer or waiter. After continuing about a year in this servile employment, he turned over the business to his brother; who marrying, and George not agreeing with his sister-in-law, he left the inn. Some time after, meeting with an old school-fellow, then a servitor in Pembroke college, Oxford, he was induced to attempt getting into the same college in a like capacity, and succeeded. Here Mr Whitefield, who from his own account appears to have always had a strong tincture of enthusiasm in his constitution from his very childhood, distinguished himself by the austerities of his devotion, and acquired considerable eminence in some religious assemblies in that city. At the age of 21, the fame of his piety recommended him so effectually to Dr Benson, then bishop of Gloucester, that he made him a voluntary officer of ordination. Immediately after this regular admission into the ministry, Mr Whitefield applied himself to the most extraordinary, the most indefatigable duties of his character, preaching daily in prisons, fields, and open streets, wherever he thought there would be a likelihood of making profelytes. Having at length made himself universally known in England, he embarked for America, where the tenets of Methodism began to spread very fast under his friends the Wesleys; and first determined upon the institution of the orphan-house at Georgia, which he afterwards effected. After a long course of peripatation, his fortune increased as his fame extended among his followers, and he erected two very extensive buildings for public worship, under the name of *tabernacles*; one in Tottenham-Court Road, and the other in Moorfields. Here, with the help of some assistants, he continued for several years, attended by very crowded congregations, and quitting the kingdom only occasionally. Besides the two tabernacles already mentioned, Mr Whitefield, by being chaplain to the countess dowager of Huntingdon, was connected with two other religious meetings, one at Bath, and

White-
ven,
Whitehead.

the other at Tunbridge, chiefly erected under that lady's patronage. By a lively, fertile, and penetrating genius, by the most unwearied zeal, and by a forcible and persuasive delivery, he never failed of the desired effect upon his ever crowded and admiring audiences. America, however, which always engaged much of his attention, was destined to close his eyes; and he died at Newberry, about 40 miles from Boston in New England, in 1770.

WHITEHAVEN, a sea-port town of Cumberland, with a market on Thursdays, and one fair on August 1st, for merchandise and toys. It is seated on a creek of the sea, on the north end of a great bergh or hill, washed by the tide of flood on the west side, where there is a large rock or quarry of hard white stone, which gives name to the place, and which, with the help of a strong stone wall, secures the harbour, into which small barks may enter. It is lately much improved in its buildings, and noted for its trade in pit-coal and salt, there being near it a prodigious coal-mine, which runs a considerable way under the sea. They have a customhouse here; and they carry on a good trade to Ireland, Scotland, Chester, Bristol, and other parts. It is 10 miles south-west of Cockermouth, and 289 north-west of London. W. Long. 3. 6. N. Lat. 54. 30.

WHITEHEAD (Paul), a celebrated satirist, the son of a taylor, was born in Westminster in the year 1710, and put apprentice to a woollen-draper. Unhappily he became acquainted with Mr Fleetwood the manager of Drury-lane theatre; who, in one of his difficulties, prevailed on Whitehead to become joint security with him for the payment of 3000 l. which Fleetwood failing to discharge, his deluded friend was reduced to take refuge in the liberties of the Fleet-prison for a considerable time. It was principally owing to him that the town was well diverted with the burlesque procession calculated to ridicule the anniversary parade of the society of Free Masons; whose public appearance has been discontinued from that time. He was very active on the part of Sir George Vandeput in the famous contested Westminster election in 1749; frequently heading numerous bodies of electors in person, and supplying the press with electioneering squibs. He was indeed generally reputed a rank Tory, heightened with a strong tincture of the Jacobite; for which supposition the frequent sneers at the House of Hanover, to be met with in his writings, furnished no small countenance. But if we pay any regard to the spirit of independence and public virtue he likewise manifests, his attachment to tyrants from principle may justly be questioned. The truth seems to be, that having a turn to satire, the party he adhered to was as much owing to accident as to choice: whether such conduct is consistent with any valuable principle, is another question. Sir Francis Dashwood, since lord Le Despencer, became Mr Whitehead's patron; and when he rose to power under lord Bute, he procured a patent place of 800 l. a-year for his favourite bard, which he enjoyed to his death in 1774. He bestowed among other legacies, the uncommon one of his heart, to his noble friend; who deposited it in a solemn manner, in a mausoleum erected for that purpose in his garden at High Wycomb in Buckinghamshire. His principal writings are,

Whitlock
Whites.

Whiting
Wickliff.

Manners, a satire; Honour, a satire; the State Dunces, a satire; the Gymnasiad, a mock heroic poem; and an Epistle to Dr Thompson: his smaller pieces in prose and verse are numerous; but he could never be prevailed on to collect and publish them. He spent three days before his death in burning MSS.

WHITELOCKE (Bulstrode), an eminent politician, historian, and lawyer, was the son of Sir James Whitelocke, knight, one of the judges, and was born at London in 1605. He was educated in grammar-learning in Merchant-Taylors school, and became a gentleman-commoner in St John's college in Oxford; but before he had taken a degree, went to the Middle Temple, where he became eminent for his skill in the common law. In the beginning of the long parliament he was chosen a burgess for Marlow in Bucks, and was appointed chairman of the committee for drawing up the charge against the earl of Strafford, and one of the managers against him at his trial. He was appointed one of the lay-gentlemen to sit among the assembly of divines; in which he made a speech concerning the *jus divinum* of church government by presbytery. In 1648 he retired into the country, that he might not have any concern in the king's trial. In 1649 he was constituted keeper of the king's library and medals, which in 1647 he had hindered from being sold. In 1653 he went ambassador to Sweden. In 1656 he was chosen speaker of the house of commons *pro tempore*; and the year following was summoned by Oliver the Protector to sit in the other house, by the name of *Bulstrode lord Whitelocke*. In 1659 he was president of the council of state, and one of the *committees of safety*. He soon after retired into the country, where he spent the remainder of his days. He died in 1676. We are told that he acquitted himself with great success and reputation in all his employments, foreign and domestic. Several of his speeches were published; and beside his *Memorials of the English affairs*, he wrote many other pieces. Lord Clarendon has left this testimony in favour of Mr Whitelocke; whom, numbering among his early friends in life, he calls, "a man of eminent parts and great learning out of his profession, and in his profession of signal reputation. And though, (says the noble historian,) he did afterward bow his knee to Baal, and so swerved from his allegiance, it was with less rancour and malice than other men. He never led, but followed; and was rather carried away with the torrent than swam with the stream; and failed through those infirmities, which less than a general defection and a prosperous rebellion could never have discovered." Lord Clarendon has elsewhere described him, as from the beginning concurring with the parliament, without any inclinations to their persons or principles; and, says he, "he had the same reason afterwards not to separate from them. All his estate was in their quarters; and he had a nature that could not bear or submit to be undone: though to his friends, who were commissioners for the king, he used his old openness, and professed his detestation of all the proceedings of his party, yet could not leave them."

WHITENESS, the quality which denominates or constitutes a body white.

WHITES, or FLUOR ALBUS. See MEDICINE, n° 364.

WHITING, in ichthyology. See GADUS.

WHITSUNDAY, a solemn festival of the Christian church, observed on the fiftieth day after Easter, in memory of the descent of the Holy Ghost upon the apostles in the visible appearance of fiery cloven tongues, and of those miraculous powers which were then conferred upon them.

It is called *Whitsunday*, or *White-Sunday*; because this being one of the stated times for baptism in the ancient church, those who were baptised put on white garments, as types of that spiritual purity they received in baptism. As the descent of the Holy Ghost upon the apostles happened upon the day which the Jews called *Pentecost*, this festival retained the name of *Pentecost* among the Christians.

WHITSUNDAY *Isle*, one of the New Hebrides, which lies about four miles to the south, runs in the same direction, and is of the same length, having more sloping exposures than Aurora: it appears to be better inhabited, and to contain more plantations.

WIBURG, a considerable town of Denmark, in North Jutland, with a bishop's see, remarkable for being the seat of the chief court of justice in the province. The hall where the council assemblies has the archives of the country, and escaped the terrible fire that happened in the year 1726, and which burned the cathedral-church, that of the Black Friars, the town-house, and the bishop's palace; but they have all been rebuilt more magnificent than before. It is seated on the lake Weter, in a peninsula, 25 miles north-west of Sleswick, and 110 north-by-west of Copenhagen. E. Long. 10. 16 N. Lat. 56. 50.

WICKER, a twig of the osier shrub single or wrought.

WICKET, a small door in the gate of a fortified place, &c. or a hole in a door through which to view what passes without.

WICKLIFF (John), the first divine in Europe who had the sense, honesty, and resolution, to attempt a reformation of religion, was born about the year 1324, in the parish of Wycliff, near Richmond, in Yorkshire. He was educated at Oxford, first in Queen's, and afterwards in Merton college, of which he was a probationer-fellow. Having acquired the reputation of a man of great learning and abilities, in 1361 he was chosen master of Baliol hall, and in 1365 constituted warden of Canterbury college, by the founder archbishop Simon de Lisle; but was, 1367, ejected by the regulars, together with three secular-fellows. He thought their proceedings arbitrary, and therefore appealed to the pope; but instead of obtaining redress, in 1370 the ejection was confirmed. This disappointment probably contributed somewhat towards his enmity to the see of Rome, or rather to confirm that enmity; for he had long before written against the pope's exactions and corruptions of religion. However, his credit in the university continued; for having taken the degree of doctor in divinity, he read public lectures with great applause; in which he frequently exposed the impositions of the Mendicant friars. About this time he published a defence of his sovereign Edward III. against the pope, who had insisted on the homage to which his predecessor king John had agreed. This defence was the cause of Wickliff's introduction at court, and of his being sent

sent one of the ambassadors in 1374, to Bruges where they met the pope's nuncios, in order to settle several ecclesiastical matters relative to the pope's authority. In the mean time Wickliff was presented by the king to the rectory of Lutterworth in Leicestershire, and in 1375 he obtained a prebend in the church of Westbury in Gloucestershire. Wickliff continued hitherto, without molestation, to oppose the papal authority; but in 1377 a bull was sent over to the archbishop of Canterbury, and to Courtney bishop of London, ordering them to secure this arch-heretic, and lay him in irons: at the same time the pope wrote to the king, requesting him to favour the bishops in the prosecution: he also sent a bull to Oxford, commanding the university to give him up. Before these bulls reached England Edward III. was dead, and Wickliff, protected by John duke of Lancaster, uncle to Richard II. favoured by the queen-mother, and supported by the citizens of London, eluded the persecution of pope Gregory IX. who died in 1378. In the following year this intrepid reformer presented to parliament a severe paper against the tyranny of Rome, wrote against the papal supremacy and infallibility, and published a book *On the truth of the scriptures*, intended to prepare the way for an English translation of them, in which he had made considerable progress. In 1381 he published *Sixteen Conclusions*; in the first of which he ventured to expose the grand article of transubstantiation. These conclusions being condemned by the chancellor of Oxford, Wickliff appealed to the king and parliament; but being deserted by his unsteady patron the duke of Lancaster, he was obliged to make a confession at Oxford; and by an order from the king was expelled the university. He now retired to his living of Lutterworth, where he finished his translation of the bible. This version of the bible, of which there are several manuscript copies in the libraries of the universities, British Museum, &c. is a very literal translation from the Latin vulgate. In 1383 he was suddenly struck with the palsy; a repetition of which put an end to his life in December 1384. He was buried in his own church, where his bones were suffered to rest in peace till the year 1428, when, by an order from the pope, they were taken up and burnt.— Besides a number of works that have been printed, he left a prodigious number of manuscripts; an accurate list of which may be seen in bishop Tanner's Bib. Brit. Hib. Some of them are in the Bodleian Lib. others in the Brit. Museum, &c.

Wickliff was doubtless a very extraordinary man, considering the times in which he lived. His natural sagacity discovered the absurdities and impositions of the church of Rome, and he had the honesty and resolution to promulgate his opinions, which a little more support would probably have enabled him to establish: they were evidently the foundation of the subsequent reformation.

WICKLOW, a county of Ireland, in the province of Lunsler, bounded by Wexford on the south; that of Dublin and part of Kildare on the north; St George's channel on the east; and Kildare and Catherlogh counties on the west. Its length, where longest, is 36 miles, and its greatest breadth 28. It is divided into six baronies. There are some pretty high mountains in this county; in one of which there

is a copper-mine, wrought at the expence of some English gentlemen. The lowlands are pretty well inhabited, enclosed and cultivated, the soil being good and the air wholesome. From the mountains in this county, one may see, in a clear day, very distinctly the mountains of Snowdon in North Wales. In the Wicklow mountains are also some of those deep dark vallies called *glyn*, very beautiful and picturesque, together with some grand and astonishing water-falls. Among the former, the dark glyn and the glyn of the mountains, are particularly remarkable. "The dark glyn," (says the author of the *Hibernia Curiosa*), is much visited in the summer-season by the gentry from Dublin, and most of the people of fortune that come to this city. It is equal, if not superior, to any of the kind in the kingdom, one of the deepest, and at the same time the narrowest and most irriguous vallies I remember to have seen. The sides of the hills which skirt it, adorned with trees to the very tops, and intermixed with rocky precipices, together with the murmuring of a little river at the bottom, that winds its way through this intricate valley over numberless little breaks and falls, that add greatly to the beauty of the scene, render it altogether a most pleasing summer recreation. The closeness of the lofty shading hills on the sides, at the same time that it affords a most delightful cool retreat from the heat of the sun, throws a kind of gloomy solemnity on the bottom of this deep valley; and from this circumstance it is very properly called the *dark glyn*. It is rather a deep chasm than a valley, extending about a mile through a lofty range of hills. At the very bottom of the glyn is a way cut out by the side of the stream, and adapted to the gloomy retirement of the place, where the lover, the poet, or philosopher, may wander, with every circumstance, every scene about him, calculated to warm his imagination, or produce the most serious reflections. The glyn of the mountains in this neighbourhood is a more open and spacious valley, but immensely deep, and skirted on either hand with the most enormous astonishing mountains, covered for the most part with trees from their bottoms to the very tops, presenting a prospect of the most horrible impending rocks. The bottom of the valley is just wide enough for a road and a river that runs through it. There is something inexpressible striking, beautiful, grand, and awful in this scene." These glyn are not far from Powerscourt, a most beautiful seat, 14 miles from Dublin, belonging to and giving the title of viscount to the family of Wingfield. Near this charming seat is one of the most beautiful water-falls in the world, called the *Fall of Powerscourt*; which, from the peculiarity of its situation, its prodigious height and singular beauty, well deserves the notice of every traveller. It is produced by a small river arising from springs and rains collected on the plains or shallow vallies, on the top of an adjacent range of mountains, and falls at least 300 feet, of which 200 are visible on the plain below. The only time to see this most beautiful and astonishing water-fall in its highest perfection is immediately after heavy rains on the mountains above. No description can then convey an adequate idea of the beauty and grandeur of the scene, or the transport of the spectator. The trees, which grow from the bottom to the top of the hill on the sides of this prodigious

water-

Widgeon
Wight.

water-fall, are an inexpressible addition to its charms. The whole scenery indeed, above and below, is the most extraordinary and entertaining of its kind that can be conceived. This county sends 10 members to parliament, viz. two for the shire, and two for each of these boroughs, Wicklow, Baltinglass, Carysfort, and Blessington.

Wicklow gives name to the county, and is its capital. This town is noted for the best ale in Ireland. It has barracks for three companies of foot, and a kind of castle and haven at the mouth of the river Leitrím; but most of its trade consists in carrying provisions in small vessels to Dublin. It gives the title of baron to lord Maynard.

WIDGEON, in ornithology. See ANAS.

WIDOW, a woman who has lost her husband.

WIFE, a married woman, or one joined with, and under the protection of an husband. See HUSBAND.

Ile of WIGHT, a part of the county of Southampton, separated from the rest by a channel about 20 miles long and 12 broad. It seems to have been called by the Britons *Uia*, the diminutive of *Uiz*, which signifies an island. Hence the Romans, imitating, as their custom was, the sound of the British word, styled it *Vidui*, *Vetui*, and *Veſta*. Diodorus Siculus, coming near to the British name, calls it *Via*. The Saxons, *Wibi*, or *White*, and *Wightland*, because possessed by the Jutes, called sometimes *Vita* and *Viti*, as well as *Juti*; whence, in the modern Welsh, it appears to be styled *Gauib*, which, because it signifies disjoined or divorced, some have thought a very significant appellation; but the former account, though more modern, is however more natural, and therefore seems to come nearer the truth.

It is separated from Hampshire by a small arm of the sea, called anciently the *Solent*, which is, in some places, 12, in others seven, in most about four miles broad, except at the strait between Sharpnor and Hurst castles, where it is not quite two. This island is, or rather was, of an oval form, and thence said to resemble an egg; and in length, from east to west, was anciently 30 miles, at present 23 at most; in breadth, from north to south, 12; in circumference, 60. The south side of the island, which is opposed to France, is naturally fortified by exceeding steep cliffs; and wherever these are wanting, forts and blockhouses have been built.

There are also large and dangerous banks of sand on the north side, called the *Horse*, *No Man's Land*, and the *Brambles*; on the west side a long ridge of rocks, and nearer the shore the needles; on the south Atherfield rocks, Challarme, and Done Moſs; to the east, the Black Rocks, the Mixon, and the White Cliff, afford a kind of natural and effectual barrier against all invaders.

It looks as if these rocks, shoals, and sands, were remnants of the land belonging to this island when 30 miles long, and shaped like an egg, as ancient authors describe it.

A long ridge of hills runs from west to east. The country on the south side is wonderfully rich and fertile, producing vast quantities of excellent corn; some say, in one good year as much as will serve the inhabitants seven. The middle and mountainous part of the island has some wood, and abundance of fine grass,

which nourishes a vast number of sheep; and their fleece is not inferior to any in Great Britain, except those of Cotswould and Lempſter. Cattle, fowl, and fish, are equally good, and, except in time of war, when the island is crowded with people, cheap. There were likewise two parks, but one of these is now converted into arable land, and a forest stored with excellent venison; to which when we add, that the climate is so mild, that myrtles grow in the open air, and so wholesome (except towards the eastern extremity, where agues are very common) that the people are generally healthy, and live frequently to a great age, we may be justified in saying, that few places can boast of being more plentiful or more pleasant.

It is admirably watered in every part by springs, brooks, or rivers. The famous road of St Helens lies on the north-east side of the island, where the sea enters so deep, as almost to cut off one part; the most eastern promontory of which is Benbridge Point, and that extremity obtains the name of *Benbridge Isle*. There is another large opening about the middle, on the north side, where the river Cowes falls into the sea, and forms a harbour, defended formerly by two strong castles, called the *East* and *West Cowes*; but the latter only is now standing. About four miles up the river stands Newport, the capital of the isle, in which there are at present between 3000 and 4000 inhabitants: It is a neat town, built with stone, to which vessels of a small burden come up; and being called in Latin *Medena*, the island is on that account divided into the Hundreds of East Meden and West Meden. About a mile from thence stands Carebrook castle upon an high rock. To the west of Newport-haven lies that of Newton, which, notwithstanding it is now inconsiderable, was heretofore also a pretty good town; and still farther to the west lies the castle and town of South Yarmouth, where the sea enters again into the land, and penetrates within a mile of the south coast. The island being here as much intersected as at the eastern extremity, as that is styled *Benbridge*, so this is called *Freshwater Isle*.

WILDERNESS, in gardening, a kind of grove of large trees in a spacious garden, in which the walls are commonly made, either to intersect each other in angles, or have the appearance of meanders and labyrinth.

WILKINS (Dr John), a most ingenious and learned English bishop, was the son of a goldsmith of Oxford, and was born in 1614. He adhered to the parliament during the civil wars, by whom he was made warden of Wadham college in 1648: he married afterwards the sister of Oliver Cromwell, and procured a dispensation to retain his wardenship notwithstanding. Richard Cromwell made him master of Trinity college, Cambridge, from which he was ejected on the Restoration. He then became preacher to Gray's Inn, rector of St Laurence Jewry, London, dean of Rippon, and in 1668 was promoted to the bishopric of Chester: he died in 1672. Bishop Wilkins thought it prudent to submit to the powers in being; he therefore subscribed to the solemn league and covenant while it was enforced, and was equally ready to swear allegiance to king Charles when he was restored; this, with his moderate spirit toward dissenters, rendered him not very agreeable to churchmen. His mathematical

Wight
Wilkins

tical and philosophical works, which contain many ingenious and curious pieces, considering the time when they were wrote, have been collected in one vol. 8vo. He published also some theological tracts.

WILL, that faculty of the mind by which it embraces or rejects any thing offered to it. See *METAPHYSICS*, n^o 76, 78, 80.

WILL, or *Legg WILL*, in law, signifies the declaration of a man's mind and intent relating to the disposition of his lands, goods, or other estate, or of what he would have done after his death. In the common law there is a distinction made between a will and a testament: that is called a *will* where lands or tenements are given; and when the disposition concerns goods and chattels alone, it is termed a *testament*. See *TESTAMENT*.

WILL-with-a-whisp, or *Jack with-a-lantern*, two popular names for the meteor called *ignis fatuus*. See *LIGHT*, n^o 27.

WILLIAM of MALMSBURY, an historian of considerable merit in the reign of king Stephen; but of whose life few particulars are known. According to Bale and Pits, he was surnamed *Somersetus*, from the county in which he was born. From his own preface to his second book *De regibus Anglorum*, it appears that he was addicted to learning from his youth; that he applied himself to the study of logic, physics, ethics, and particularly to history. He retired to the Benedictine convent at Malmesbury, became a monk, and was made precentor and librarian; a situation which especially favoured his intention of writing the history of this kingdom. In this monastery he spent the remainder of his life, and died in the year 1142. He is one of our most ancient and most faithful historians. His capital work is that intitled *De regibus Anglorum*, in five books; with an Appendix, which he styles *Historia Novelle*, in two more. It is a judicious collection of whatever he found on record relative to England, from the invasion of the Saxons to his own times.

WILLIAM of Newbury, so called from a monastery in Yorkshire, of which he was a member, wrote a history which begins at the conquest, and ends at the year 1197. His Latin style is preferred to that of Matthew Paris; and he is intitled to particular praise, for his honest regard to truth, in treating the fables of Jeffery of Monmouth with the contempt they deserve; as well as for expressing his approbation of Henry II's design of reforming the clergy, by bringing them under the regulation of the secular power.

WILLIAM of Poitiers, chaplain to king William the Conqueror, wrote a fair account of the Norman revolution, that has found good credit with most of our historians.

WILLIAM, archbishop of Tyre, was a learned prelate, who in the reign of Henry II. was sent to explore all the powers of Europe to aid the Holy Land by a new crusade. He has left *A History of the Holy Wars*, from their commencement to the year 1183, which in matter and style is far superior to any other of that or many preceding ages.

WILLIAM of Wykeham, bishop of Winchester, was born in the village of Wykeham, in the county of Southampton, in 1324. He had his education at Winchester and Oxford. Having continued near six

years in the university, his patron Nicholas Wedal, governor of the province of Southampton, took him into his family, and appointed him his counsellor and secretary. He could not have made choice of a fitter person for that employment, no man in that age writing or speaking more politely than Wykeham. For this reason Edington, bishop of Winchester, lord high-treasurer of the kingdom, appointed him his secretary three years after, and also recommended him to king Edward III. who took him into his service. Being skilled in geometry and architecture, he was appointed surveyor of the royal buildings, and also chief-justice in Eyre: he it was who superintended the building of Windsor-castle. He was afterward chief secretary of state, and keeper of the privy-seal; and in 1367 succeeded Edington in the see of Winchester. A little after he was appointed lord high-chancellor and president of the privy-council. That he might well discharge the several functions of his employments, both ecclesiastical and civil, he endeavoured, on one hand, to regulate his own life according to the strictest maxims, and to promote such parish-priests only as were able to give due instructions to their parishioners, and at the same time led exemplary lives: on the other hand, he did all in his power to cause justice to be exactly administered. In 1371 he resigned his chancellorship, and some time after the great seal. Edward being returned to England, after having carried on a very successful war in France, found his exchequer in great disorder. The duke of Lancaster, one of his sons, at the head of several lords, having brought complaints against the clergy, who then enjoyed most power in the kingdom, the king removed them from their employments. But the laymen, who were raised to them, behaved so ill, that the king was forced to restore the ecclesiastics. The duke of Lancaster showed strong animosity to the clergy, and set every engine at work to ruin Wykeham. He impeached him of extortion, and of disguising things, and obliged him to appear at the King's-bench. He got such judges appointed as condemned him; and not satisfied with depriving him of all the temporalities of his bishopric, he advised Edward to banish him: but this prince rejected the proposal, and afterward restored to Wykeham all that he had been divested of. Richard II. was but eleven years old when Edward died; whereby the duke of Lancaster had an easy opportunity of reviving the accusations against the bishop of Winchester: nevertheless Wykeham cleared himself. Then he founded two noble colleges, the one in Oxford, the other in Winchester. Whilst he was exerting his utmost endeavours to improve these two fine foundations, he was recalled to court, and in a manner forced to accept of the office of lord high-chancellor in 1389.—Having excellently discharged the duties of that employment for three years, he obtained leave to resign it, foreseeing the disturbances that were going to break out. Being returned to his church, he finished his college, and built there so magnificent a cathedral, that it almost equals that of St Paul's in London. He laid out several sums in things advantageous to the public and to the poor; notwithstanding which, in 1397 he was in great danger; for he and some others were impeached of high-treason in open parliament; however, he was again fully cleared. From that time

William
Willis.

till his death he kept quiet in his diocese, and there employed himself in all the duties of a good prelate. He died in 1404, in the 81st year of his age.

WILLIAM, the name of several kings of England. See ENGLAND, n° 86. 91. and BRITAIN, n° 280, &c.

WILLIAMSBURG, the capital of Virginia in North America, situated in James county, between James and York rivers. W. Long. 76. 30. N. Lat. 37. 20.

WILLIAM'S FORT, is a factory of Asia belonging to the East-India company, seated on one of the branches of the river Ganges, in the kingdom of Bengal. The fort was first built in the shape of an irregular tetragon of brick and mortar; and the town has nothing regular in it, because every one built a house as he liked best, and for his own convenience. The governor's house is within the fort, and is the best piece of architecture in these parts. Here there are also convenient lodgings for the factors and writers, with store-houses for the company's goods, and magazines for ammunition. About 50 yards from the fort is the church, built by the charity of merchants residing here. The town is called *Calcutta*, and has a pretty good hospital for the sick, though few come out of it alive. It is governed by a mayor and aldermen, as most of the company's factories in the East Indies now are. In 1757 it was surprised by the nabob of Bengal, who took it, and put most of those that had made resistance into a place called the *Black Hole*, where most of them were smothered. This nabob was afterwards killed, and another set up in his room, more friendly to the English; and the factory was re-established. E. Long. 86. 0. N. Lat. 22. 27.

WILLIAMSTADT, a sea-port town of Holland. It is a handsome strong place, and the harbour is well frequented. It was built by William prince of Orange in 1585; and in 1732 belonged to the stadtholder of Friesland. The river near which it is built is called *Butterfleet*, or *Holland Diep*; and is one of the bulwarks of the Dutch on the side of Brabant, where they always keep a garrison. E. Long. 4. 23. N. Lat. 51. 41.

WILLIS (Dr Thomas), a celebrated English physician, was born at Great Bodwin, in Wiltshire, in 1621, and studied at Christ-church college, Oxford. When that city was garrisoned for the king, he, among other scholars, bore arms for his Majesty, and devoted his leisure hours to the study of physic. The garrison of Oxford at length surrendering to the parliament, he applied himself to the practice of his profession; and soon rendered himself famous by his care and skill. He appropriated a room as an oratory for divine service according to the church of England, whither most of the loyalists in Oxford daily resorted. In 1660, he became Sedleian professor of natural philosophy, and the same year took the degree of doctor of physic. In 1664, he discovered the famous medicinal spring at Alstropp, near Brackley. He was one of the first members of the Royal Society, and soon made his name illustrious by his excellent writings. In 1666, after the fire of London, he removed to Westminster; and his practice became greater than that of any of the physicians his contemporaries. Soon after his settlement in London, his only son Thomas falling into a consumption, he sent him to Montpellier in

France for the recovery of his health; and it proved successful. His wife also labouring under the same disorder, he offered to leave the town; but she, not suffering him to neglect the means of providing for his family, died in 1670. He died at his house in St Martin's in 1675, and was buried near her in Westminster abbey. Dr Willis was extremely modest and unambitious, and refused the honour of knighthood. He was remarkably pious: As he rose early in the morning, that he might be present at divine service, which he constantly frequented before he visited his patients, he procured prayers to be read beyond the accustomed times while he lived; and at his death settled a stipend of 20*l. per annum* to continue them. He was a liberal benefactor to the poor wherever he came, having from his early practice allotted part of his profits to charitable uses. He was exact and regular in all his hours; and though his table was the resort of most of the great men of London, yet he was remarkable for his plainness, and his being a man of little discourse, complaisance, or society; but he was justly admired for his deep insight into natural and experimental philosophy, anatomy, and chemistry; for his successful practice; and for the elegance and purity of his Latin style. He wrote, 1. A treatise in English, intitled *A plain and easy Method for preserving those that are well from the Infection of the Plague, and for curing such as are infected.* 2. Several Latin works, which were collected and printed at Amsterdam, in 1682, in 2 vols, 4to.

WILLIS (Brown), grandson of the famous physician, and an eminent antiquary, was born in Dorsetshire in 1682. He was educated in Westminster school, where the solemnity of the adjoining abbey engaged his admiration, and impressed his mind with an early love of antiquities. From thence he removed to Christ-church, Oxford; and during the course of his life visited almost all the cathedrals in England and Wales; which journeys he used to call his *pilgrimages*. He published Surveys of them in 4 vols, 4to. He wrote also A History of the mitred Parliamentary Abbeys, 2 vols, 8vo; and *Notitia Parliamentaria*, 2 vols, 8vo; with some other things. He was chosen member for the town of Buckingham in 1705; was created doctor of laws at Oxford in 1749, and died in 1760.

WILLOUGHBY (Francis), a celebrated natural historian, was the only son of Sir Francis Willoughby, knight. He was fond of study from his childhood, and held idleness in abhorrence; he being so great an economist with regard to his time, as not willingly to lose or misapply the least part of it; by which means he attained great skill in all branches of learning, and particularly in the mathematics: but observing that the history of animals was in a great measure neglected by his countrymen, he particularly applied himself to that province; and for this purpose carefully read over what had been written on that subject by others. He then travelled several times over his native country; and afterwards into France, Spain, Italy, Germany, and the Low Countries, attended by his ingenious friend Mr John Ray. It is remarkable, that, notwithstanding the advantages of birth, fortune, and parts, he was as humble as any man of the meanest fortune; was sober, temperate, and chaste; scrupulously just; so true to his word and promise, that a

Willis
Willoughby.

man might venture his estate and life upon it; so faithful and constant to his friend, as never to desert him when fortune frowned upon him; and remarkably pious, patient, and submissive to the divine will. This is the character given of him by Mr Ray, whose veracity none will doubt. This ingenious and learned gentleman died in 1672, at 37 years of age; having impaired his health by his application. He wrote, 1. *Ornithologia libri tres*, folio, which was afterwards translated into English, with an Appendix by Mr Ray, in folio. 2. *Historia Piscium libri quatuor*, folio. 3. Letters of Francis Willoughby, Esq; added to Philosophical Letters between the learned Mr Ray and several of his correspondents, published, in 8vo, by William Derham. 4. Several ingenious papers in the Philosophical Transactions.

WILMOT (John), earl of Rochester, a great wit in the reign of Charles II. the son of Henry earl of Rochester, was born in 1648. He was taught grammar and classical learning at the free-school at Burford; where he obtained a quick relish of the beauties of the Latin tongue, and afterwards became well versed in the authors of the Augustine age. In 1659, he was admitted a nobleman of Wadham college, where he obtained the degree of master of arts. He afterwards travelled through France and Italy; and at his return was made one of the gentlemen of the bed-chamber to the king, and comptroller of Woodstock Park. In 1665, he went to sea, and was in the Revenge, commanded by Sir Thomas Tiddiman, when the attack was made on the port of Bergen in Norway; during the whole action he showed the greatest resolution, and gained a high reputation for courage; which he supported in a second expedition, but afterwards lost it in a private adventure with Lord Mulgrave.

Before the earl of Rochester travelled, he had given into the most disorderly and intemperate way of living; yet he had so far got the better of it at his return, that he hated nothing more. But falling into the company of the courtiers, who continually practised these excesses, he became so sunk in debauchery, that he was for five years together so given up to drinking, that during all that time he was never cool enough to be master of himself. His violent love of pleasure, and his disposition to extravagant mirth, carried him to great excesses. The first involved him in sensuality, and the other led him into many adventures and ridiculous frolics. Once disguising himself so that he could not be known by his nearest friends, he set up in Tower-street for an Italian mountebank, and there dispersed his nostrums for some weeks. He often disguised himself as a porter, or as a beggar, sometimes to follow a mean amour: at other times, he would go about merely for diversion, in odd shapes; and acted his part so naturally, that he could not be known even by his friends. In short, by his constant indulgence in wine, women, and irregular frolics, he entirely wore out an excellent constitution before he was 30 years of age. In October 1679, when recovering from a violent disease, which ended in a consumption, he was visited by Dr Burnet, upon an intimation that such a visit would be agreeable to him. Dr Burnet published an account of his conferences with Lord Rochester; in which it appears, that though he had lived the life of a libertine and atheist, yet he died the death of a penitent Christian.

His death happened in 1680; since which time his poems have been various times printed, both separately and together: but when once he obtained the character of a lewd and obscene writer, every thing in that strain was fathered upon him; and thus many pieces not of his writing have crept into the later editions of his works. The author of the Catalogue of Royal and Noble Authors, says, he was "a man whom the Muses were fond to inspire, and ashamed to avow, and who practised without the least reserve that secret which can make verses more read for their defects than their merits. Lord Rochester's Poems have much more obscenity than wit, more wit than poetry, and more poetry than politeness. One is amazed at hearing the age of Charles II. called polite; because the Presbyterians and religionists had affected to call every thing by a Scripture name. The court had no pretensions to politeness, but by its resemblance to another age, which called its own grossness polite, the age of Aristophanes. Would a Scythian have been civilized by the Athenian stage, or a Hottentot by the drawing-room of Charles II.? The characters and anecdotes being forgot, the state-poems of that time are a heap of senseless ribaldry, scarcely rhyme, and more seldom in metre. When Satyrs were brought to court, no wonder the Graces would not trust themselves there." His writings, besides those already mentioned, are, a Satyre against Mankind; Nothing, a poem; Valentinian, a tragedy; Fifty-four Letters to Henry Saville, and others; Seven more to his Wife and Son; a Letter on his deathbed to Dr Burnet. He also left behind him several other papers, and a History of the Intrigues of the Court of Charles II. but his mother, a very devout lady, ordered all his papers to be burned.

WILSON (Florence), known in the republic of letters by the name of *Florentius Volusinus*, was born at Elgin in the shire of Murray in Scotland, and educated in the university of Aberdeen. Travelling to England with an intention to improve his fortune, he had the felicity to be introduced to cardinal Wolsey, who appointed him tutor to one of his nephews. In that capacity he went to Paris, and continued there till the cardinal's death. During his residence in that city he became acquainted with the learned cardinal Bellai, archbishop of Paris, who allowed him a pension, and meant to have appointed him royal professor of the Greek and Latin languages in the university of Paris: but Bellai being disgraced, Wilson's prospects faded with the fortunes of his patron, whom nevertheless he attended on his journey to Rome. Wilson was taken ill at Avignon, and the cardinal proceeded without him. After his recovery, he paid a visit to the celebrated cardinal Sabote, the Mecenas of his time, who was also bishop of Carpentras, where he then resided. The cardinal was so charmed with his erudition, that he appointed him professor of the learned languages, with a stipend of 100 pistoles *per annum*.

During his residence at Carpentras, he wrote his celebrated treatise *De animi tranquillitate*. Mackenzie says that he afterwards taught philosophy in Italy; and that, being at length desirous of returning to Scotland; he began his journey homeward, was taken ill at Viene in Dauphiny, and died there in the year 1547. He was generally esteemed an accomplished linguist.

Wilmot,
Wilson.

Wilson.

an admirable philosopher, and an excellent Latin poet. He wrote, beside the above treatise, 1. *Poemata*. Lond. 1619, 4to. 2. *Commentatio quadam theologica in aphorismos dissecta, per Sebast. Gryph.* 3. *Philosophie Aristot. synopsis*, lib. iv.

WILSON (Thomas), lord bishop of Sodor and Man, was born in 1663, at Burton, in the county of Cheller. He received the rudiments of his education at the county town, and from thence was removed to the university of Dublin. His allowance at the university was 20l. a-year; a sum, small as it may now appear, which was in those days sufficient for a sober youth in to cheap a country as Ireland.

His first intention was to have applied to the study of physic; but from this he was diverted by archdeacon Hewetson, by whose advice he dedicated himself to the church. He continued at college till the year 1686, when, on the 29th of June, he was ordained deacon.

The exact time of Mr Wilson's leaving Dublin is not known: but on account of the political and religious disputes of those days, it was sooner than he intended. On the 10th of December in the same year, he was licensed to the curacy of New Church in Winkwick, of which Dr Sherlock, his maternal uncle, was rector. His stipend was no more than 30l. a-year; but being an excellent economist, and having the advantage of living with his uncle, this small income was not only sufficient to supply his own wants, but it enabled him to supply the wants of others; and for this purpose he set apart one-tenth of his income.

In 1692 he was appointed domestic chaplain to William earl of Derby, and tutor to his son James Lord Strange, with a salary of 30l. a-year. He was soon after elected master of the alms-house at Latham, which brought him in 20l. a-year more. Having now an income far beyond his expectations, or his wishes, except as it increased his ability to do good, he set apart one fifth of his income for pious uses, and particularly for the poor. In short, as his income increased, he increased the portion of it which was allotted to the purposes of charity. At first he set apart a tenth, then a fifth, afterwards a third, and lastly, when he became a bishop, he dedicated the full half of his revenues to pious and charitable uses.

He had not been long in the service of Lord Derby, before he was offered the valuable living of Buddsworth in Yorkshire; which he refused to accept, as being inconsistent with the resolves of his conscience against non-residence, Lord Derby choosing still to retain him as chaplain, and tutor to his son. In 1697 he was promoted, not without some degree of compulsion on the part of his patron, to the bishopric of the Isle of Man; a preferment which he held 58 years. In 1698 he married Mary, daughter of Thomas Patten, Esq; of Warrington. By this lady, who survived her marriage about six years, he had four children; none of whom are living except Dr Wilson, prebendary of Westminster.

"The annual receipts of the bishopric (says the author of his memoirs) did not exceed 300l. in money. Some necessaries in his house, as spices, sugar, wine, books, &c. must be paid for with money; distressed or shipwrecked mariners, and some other poor objects, required to be relieved with money; but the poor of the island were fed and clothed, and the house in general

supplied from his demesnes, by exchange, without money. The poor, who could weave or spin, found the best market at Bishop's-court, where they bartered the produce of their labour for corn. Taylors and shoemakers were kept in the house constantly employed, to make into garments or shoes that cloth or leather which his corn had purchased; and the aged and infirm were supplied according to their several wants. Mr Moore of Douglas informed the editor, that he was once witness to a pleasing and singular instance of the Bishop's attention to some aged poor of the island. As he was distributing spectacles to some whose eyesight failed them, Mr Moore expressed his surprise, as he well knew not one of them could read a letter.

"No matter, (said the Bishop with a smile) they will find use enough for them; these spectacles will help them to thread a needle, to mend their clothes, or, if need be, to keep themselves free from vermin."

The year 1720 brings us to a remarkable epocha in the life of this zealous and worthy Bishop; the history of which will be best related in the biographer's own words. "The suspended person alluded to in the Bishop's charge of June the 9th, 1720, was no less a person than Mrs Horn, wife of Captain Horn, governor of the island. In the year 1719, the accused Mrs Puller, a widow woman of fair character, of fornication with Sir James Pool; and from this story, to please Mrs Horn, archdeacon Horrobin refused Mrs Puller the sacrament. Uneasy under this restriction, she had recourse to the mode pointed out by the constitutions of the church to prove her innocence, namely, by oath; which she and Sir James Pool took before the Bishop, with purgators of the best character; and no evidence being produced to prove their guilt, they were by the Bishop cleared of the charge; and Mrs Horn was sentenced to ask pardon of the parties whom she had so unjustly traduced. This she refused to do; and treated the Bishop and his authority, as well as the ecclesiastical constitutions of the island, with contempt. For this indecent disrespect to the laws of the church, the ecclesiastical censure was pronounced, which banished her from the sacrament till atonement was made. The archdeacon, who was chaplain to the governor, out of pique to the Bishop, or from some unworthy motive, received her at the communion, contrary to the custom and orders of the church. An insult to himself the Bishop would have forgiven, but disobedience to the church and its laws he could not allow of. He considered it as the oblation of wrath, rather than the bond of peace, and at last suspended the archdeacon. The archdeacon in a rage, instead of applying to the archbishop of York as metropolitan, and consequently the proper judge to appeal to in matters relating to the church, threw himself on the civil power; and the governor, under pretence that the Bishop had acted illegally and extrajudicially, fined him 50l. and his two vicars-general, who had been officially concerned in the suspension, 20l. each. This fine they all refused to pay, as an arbitrary and unjust imposition: upon which the governor sent a party of soldiers; and they were, on the 29th of June 1722, committed to the prison of Castle Rushin, where they were kept closely confined, and no persons admitted within the walls to see or converse with them." The Bishop was confined in this prison two months, and

re-

shire, released at the end of that time upon his petition to the king and council."

So great was the Bishop's attachment to his flock, that no temptation could seduce him from their service. He more than once refused the offer of an English bishopric. There is an anecdote of his Lordship and cardinal Fleury, which does great credit to them both. The cardinal wanted much to see him, and sent over on purpose to inquire after his health, his age, and the date of his consecration, as they were the two oldest bishops, and he believed the poorest, in Europe; at the same time inviting him to France. The Bishop sent the cardinal an answer, which gave him so high an opinion of him, that the cardinal obtained an order that no French privateer should savage the Isle of Man.

This good prelate lived till the year 1755, dying at the advanced age of 93. His works have lately been published in 2 vols 4to.

WILTSHIRE, a county of England, bounded on the west by Somersetshire, on the east by Berkshire and Hampshire, on the north by Gloucestershire, and on the south by Dorsetshire and part of Hampshire. The length amounts to 39 miles; its breadth to 30; and its circumference to 140. It contains 29 hundreds, 23 market-towns, 304 parishes, and about 876,000 souls. Besides two members for the shire, and two for the city of Salisbury, each of the following towns sends two to parliament, viz. Wilton, Downton, Hindon, Heytesbury, Westbury, Cane, Devizes, Chippanham, Malmesbury, Cricklade, Great Bedwin, Ludgershall, Old Sarum, Wootton-Bassett, Marlborough.

The air of this county is very healthy, not only in the more low and level parts, but also on the hills. The soil of the vales is very rich, and produces corn and grass in great plenty. The beautiful downs in the south yield the finest pasture for sheep, with which they are overspread. The greatest disadvantage the county labours under is want of fuel, as there are no coal-pits, and but little wood. This county is noted for great quantities of very fine cheese, and for its manufacture of broad cloth, to which it was invited by the great plenty and fineness of its wool. Besides a number of lesser streams, it is watered by the rivers Isis, Kennet, Upper and Lower Avon, Willy, Burne, and Nadder, which are well stored with fish.

WINCHELSEA, a town in Suffex, which has no market, but has one fair on May 14, for cattle and pedlars-ware. It was an ancient place, at least the old town, which was swallowed up by the ocean in 1250. It is now dwindled to a mean place, though it retains its privileges, and sends two members to parliament. It is seated on a rocky cliff, on an inlet of the sea; and had a haven, now choked up. It had 18 parish-churches, now reduced to one. The market-house is in the midst of the town, from whence run four paved streets, at the end of which are four ways, which had formerly buildings on each side for a considerable distance. It is 2 miles south-west of Rye, and 71 south-east of London. It is governed by a mayor and jurats, though it has but about 70 houses. Three of the gates are still standing, but much decayed. E. Long. o. 45. N. Lat. 50 58.

WINCHELSEA (Anne countess of), a lady of excellent genius, especially in poetry, was maid of ho-

nour to the dukes of York, second wife to king James II. and was afterwards married to Heneage, second son of the earl of Winchelsea. One of the most considerable of the countess of Winchelsea's poems was that on the Spleen. A collection of her poems were printed at London in 1713, containing a tragedy never acted, intitled *Ariflomene*. The countess died in 1720 without issue, as her husband did in 1726.

WINCHESTER, the capital of the county of Hampshire in England. It is a very ancient city, supposed to have been built several centuries before Christ. The Romans called it *Venta Belgarum*, the Britons *Caer Givent*, and the Saxons *Wittanceaster*; whence came the present name. It stands upon the river Itchin, in a bottom surrounded with chalky hills; and is generally allowed to have been a considerable place in the time of the Romans. Some of the first converts to Christianity are supposed to have lived here. In the castle, near the west-gate, many of the Saxon kings anciently kept their court. In the hall where the affizes are kept, is shown a round table of one piece of wood, which, it is pretended, is above 1200 years old, and was that at which king Arthur, with his knights, used to carouse; but Camden says it plainly appears to be of a much more modern date. There is an inscription in Saxon characters upon it, which is now illegible, said to be the names of his 24 knights. The cathedral was founded by Kenegulf, a king of the Mercians; but there were many Christians, and places for their worship here, long before that period. Kineval, or Kenwalchius, the son of Kenegulf, translated the see of Sherburn hither, and made Wina a Frenchman the first bishop; who falling afterwards under the displeasure of Kineval, purchased the see of London from Wulphire king of Mercia, and is reckoned the first simoniacal bishop in England. Here Egbert I. sole monarch of England, was crowned; and not long after Swithin, one of the bishops of this see, was canonized. Another of the bishops of this see was Deneulf, whom Alfred preferred to it, after he had acquired a sufficient stock of learning, though he had been a swine herd, as a reward for having concealed him from the Danes. A monastery was built here by Edward the Elder; and richly endowed by him and his successors. Edward the Confessor was crowned in this place by Edius, archbishop of Canterbury. At that time Alwyn was bishop of this see; but was confined to a monastery on suspicion of a criminal correspondence with queen Emma: from which he was discharged upon the queen's clearing herself by ordeal. By way of thanksgiving to St Swithin for her deliverance, the queen gave nine manors to his church. Walkelin, the next bishop, laid the foundation of the present cathedral. William the Conqueror kept his court here; and at this place he beheaded Waltheof, the great Saxon earl of Northumberland. He not only confined for life in the castle, but put out the eyes of Ederic, another Saxon earl, because he had delivered up the castle of York to Edgar Atheling. Giffard, the next bishop, to terminate the quarrels between the monks of the old and new minsters, removed the latter to Hyde, in this neighbourhood, where he had built an abbey for their reception. His successor was Henry of Blois, brother to king Stephen; who reduced the empress Maud to such straits in this city and castle,

Winchester that she caused a report to be spread of her death, and was carried out in a coffin. The bishop after his return, founded and endowed the hospital of St Cross, about a mile to the south of this city, and built the bishop's palace called *Wolsseley*. Here Henry II. held a parliament, and was crowned with his queen. When Godfrey Lucy, son to Richard, lord chief justice of England and governor of the castle, was bishop, Richard II. granted a charter, with very ample privileges, to the citizens. King John resided in this city; and his son Henry III. was born there. Peter de la Roche, another of its bishops, was lord chief-justice and governor of the kingdom in the minority of Henry III. In his time Henry the Lion, duke of Bavaria, with his duchess Matilda, daughter of Henry II. resided at Winchester, where their son William, duke of Bavaria, was born. Hen. III. kept his Christmas here in 1239, when Raleigh was bishop. When the barons rose, the city was taken, and all the Jews in the town put to the sword; but the earl of Leicester, whose son had taken it, being slain, it was recovered by the king. After the murder of Edward II. his uncle, Edmund Plantagenet, was beheaded at the castle-gate of this city. William Edendon, bishop of this see, being elected archbishop of Canterbury, refused it, saying, "If Canterbury is the higher rack, Winchester is the better manger." This bishop, who had been treasurer of England, was buried in an alabaster tomb on the south-side of the entrance into the choir. He was succeeded by the famous WILLIAM of WICKHAM, so denominated from a village near this place, who became prime minister to Edward III. He procured a charter, by which this city was made a staple for wool; and founded a college called *St Mary's*, which he endowed with a liberal maintenance for a warden, 10 fellows, 2 masters, 70 scholars, 3 chaplains, 3 clerks, an organist, and 16 choristers, to which he granted great privileges. The college consists of two courts, in which are lodgings for the masters and scholars, &c. a large hall, chapel, schools, and a library. After a certain time of continuance in the school, the scholars, if they choose to prosecute their studies, have exhibitions for that purpose in New-college, Oxford, which was also founded by Wickham. The same prelate built also the nave of the church, and obtained the offices of chancellor to the archbishop of Canterbury, and prelate of the garter, to be annexed to this see. Besides these donations, he expended 20,000 merks in the repair of houses, mended the highways from hence to London, built several free-schools and hospitals, both in this county and Surry; all which have his coat of arms on them, with this motto, "Manners make the man." Henry IV. was married in this city; and Henry V. gave audience in it to the French ambassadors who came to implore peace. The bishop at that time was Henry de Beaufort, uncle to the king, who was thrice chancellor of the kingdom, a cardinal, and general of the Pope's forces against the Bohemians. He founded an hospital here, left legacies to all the cathedrals of England, and lies buried in a fine tomb in the church; in which he is represented in his cardinal's robes and hat. Arthur, eldest son of Henry VII. was born in this city in 1486. Waynfleet, bishop of this see, founded Magdalen college in Oxford. One of his successors, Richard Fosse, collected the bones of Ken-

gulf, Kinolphus, Egbert, Edmund, Canute, queen Emma, William Rufus, and his brother Richard, which had been dispersed in the civil wars, deposited them in leaden chests, and interred them at the foot of the great wall of the choir. In 1554 queen Mary was married in this city to Philip of Spain, and the chair used on that occasion is still preserved. In her reign the persecuting Gardiner was bishop of this see. One of his successors was Cooper, author of the *Theaurus*, which bears his name. Morley, who was bishop of this see after the Restoration, built a new episcopal palace, and a college for 10 ministers widows, which he endowed with a good revenue. In his time a palace was begun and almost finished here by Charles II. which is now going to ruins. In the monastery at Hyde was a cross, the gift of Canute the Dane, which cost him one year's revenue of all England. When the monks were ejected out of the other convent dedicated to the Holy Trinity, they were succeeded by a dean and 12 prebendaries. The cathedral is a large pile, and has a venerable look, but is not very elegant. Besides the tombs, there are many curious pieces of workmanship in it; the chief of which are, 1. The font, erected in the time of the Saxons. 2. Copper statues of James I. and Charles I. 3. The bishop's throne. 4. The stalls of the dean and prebendaries. 5. The ascent to the choir and altar. 6. The pavement, inlaid with marble of diverse colours, in various figures. 7. The altarpiece, reckoned the noblest in England. 8. The paintings in the windows, especially the great east window. At the hospital of the Holy Cross mentioned above, every traveller that knocks at the door may claim a manchet of white bread and a cup of beer; of which a great quantity is provided every day for that purpose. This hospital was intended for the maintenance of a master and 30 pensioners, but only 14 are now maintained in it; and the master enjoys a revenue of 800*l.* a-year. This city is about a mile and a half in compass, and almost surrounded with a wall of flint, has six gates, large suburbs, broad clean streets; but the private houses are in general but ordinary, many of them being very old. The city is interspersed with a great many gardens, which contribute to its beauty and healthiness. There is a great deal of good company in the city and neighbourhood, and many clergymen, but little trade or manufacture. Many other public edifices, besides those we have mentioned, adorn this city; particularly an infirmary, an hospital called *St John's*, and the guildhall. The corporation consists of a mayor, high-steward, recorder, aldermen, two coroners, two bailiffs, 24 common-council-men, a town clerk, four constables, and four sergeants at mace; and the city gives title of *marquis* to the duke of Bolton. A Roman highway leads from hence to Alton; and went formerly, as it is thought, from thence to London. The charming downs in the neighbourhood contribute greatly to the health and pleasure of the inhabitants. The river Itchin is navigable for barges from hence to Southampton.

WIND. As the air is a fluid, subjected to the same laws of gravitation as other fluids, it necessarily has a constant tendency to preserve an equilibrium in every part; so that if, by any means whatever, it is rendered lighter in any one place than another, the weightier air will rush in from every side towards this place, till

EXHIBITING

A View of the GENERAL and COASTING TRADE-WINDS, and MONSOONS or SHIFTING TRADE-WINDS, through the whole WORLD.

N. B. The arrows among the lines, show the course of the winds. The double arrows, pointing different ways, in those places where the lines are thicker than usual, denote the monsoons, the darts always pointing the way that the wind blows in the months which are written by the darts.

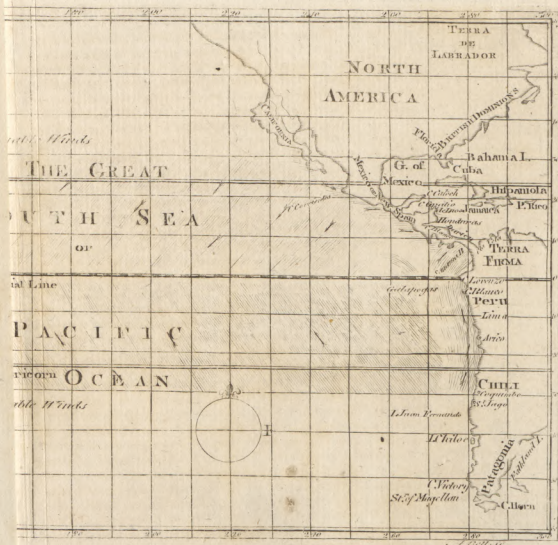

N. B. The exact point where the S. E. and N. E. trade-winds meet each other near the equator, in the Pacific Ocean, is not precisely ascertained. We have therefore discontinued the lines which denote the course of the wind on each side of the equator, at some distance from it. It is generally supposed that the south wind extends to the north of the line, as in the Atlantic Ocean: upon what authority we know not. It seems to us more probable, that this point varies according to the course of the sun; the south wind extending to the north of the line during our summer-season, and the north wind to the south of it in winter. But observations are wanting to confirm this.

Neither is it easy to ascertain with precision the exact boundaries between the invariable trade-winds and the monsoons in the Indian Ocean, near the line; or to say exactly, how far the monsoons, which take place to the south of the equator, extend west from Sumatra and Java.

T,

TRADE-WINDS, through the whole WORLD.

where the lines are thicker than usual, denote the monsoons,
 then by the darts.

retained. We have therefore discontinued the lines which denote the course
 line, as in the Atlantic Ocean: upon what authority we know not. It seems
 summer-season, and the north wind to the south of it in winter. But obser-
 ve, near the line; or to say exactly, how far the monsoons, which take place

as much be there accumulated as makes it of an equal weight with the rest of the atmosphere: it is these currents of air which are called *winds*.

Many are the causes which may vary the weight of the atmosphere, and occasion particular tropical winds.

Although other causes may occasion winds in certain circumstances, yet their principal and most universal cause is the sun, which warmeth the air to a much greater degree in some places of the atmosphere than in others; and as the air is susceptible of a great degree of expansion by heat in those places where it is heated to any considerable degree, it is expanded so much as to become lighter than the air in those places where it is colder; so that the weightier cold air from all the circumjacent parts rushes towards this point to restore the equilibrium which had been destroyed. So that if there be any particular part upon the earth's surface where the sun acts constantly with greater force than on any other part, a current of air will constantly flow from there towards the warmer region: but the sun acts with greater force upon those parts of the earth which are nearest the equator, than those which approach towards either poles; so that we might naturally expect that a wind would constantly blow from the polar regions towards the equator; which is really found to be the case in the torrid zone, where the influence of the sun overcomes almost all the other lesser causes which produce the variable winds in our more northerly regions. However, even in the torrid zone, these north and south winds are varied in different ways.

Although the heat of the equatorial region is greater than any other, yet as the sun acts perpendicularly in his diurnal course upon one point of the equator only at one time, and immediately passes over it, and as the air retains the heat communicated to it by the sun but for a short time, cooling gradually as he retires, and continuing still to decrease till his influence again returns the following day; the degree of heat upon this great circle must be very different in different parts, and perpetually varying in every point; which must in some measure tend to disturb those winds coming from the polar regions, which we have already mentioned. To comprehend clearly what will be the effects of this rotation, let us consider what effect it would naturally produce upon the equator with regard to wind, supposing no other cause should interrupt it. And here we must observe, that as the point upon which the sun acts with the greatest power is constantly moving from east to west, the air to the east of that point over which the sun has more lately passed will be more rarified than that to the west, and will naturally flow towards that point from east to west with greater velocity than from west to east, as the cool air to the west of that point will be interrupted in its motion towards it by the motion of the sun meeting it. Hence therefore it follows, that from the diurnal motion of the earth from west to east a constant wind would always be produced, were it not obstructed by other causes. But as there is a constant stream of air flowing from the polar towards the equatorial regions, a composition of these two currents of air acting at the same time will produce a north-east wind in all parts of the northern hemisphere, and a south-east wind in all parts of the southern one. These winds are known

by the name of the *general trade winds*.

If there were no inequalities on the surface of our globe, and if it were composed of a substance perfectly homogeneous, this wind would invariably take place at all times on every part of the earth's surface: but as this is not the case, it is liable to several very considerable variations. In all those regions towards the poles, as the influence of the sun is there but weak, other lesser causes occasion particular winds, and disturb that regularity which at first view we might expect; so that the general trade wind does not invariably take place beyond the 28th or 30th degree of latitude; and the regions between that and the poles have nothing but variable winds. Even in the torrid zone, there are many causes which in particular places alter this direction of the wind; so that the genuine trade-winds do not take place except in the Atlantic and Pacific oceans on each side the equator to the distance of 28 or 30 degrees, and in the greatest part of the Indian ocean to the south of the equator, as appears more distinctly upon the Map, (Plate CCCXII.) where the course of the winds are marked by the direction of the strokes, the darts pointing in the same direction as the wind blows.

Having thus explained the nature and causes of the general trade-wind, we now proceed to take notice of the principal deviations which take place in the torrid zone. The general trade-wind, when thus altered at particular seasons, is known by the name of *monsoons*. There are other variations, which, although as general, are yet of smaller and more limited influence. These are known by the name of *breezes*; and as they blow periodically from the sea, they are denominated *sea or land breezes*, and take place more or less in every sea-coast within the tropics. As the causes of the monsoons will be more clearly comprehended after the nature of these breezes is explained, we shall first consider them.

The sea and land breezes of the torrid zone are gentle periodical winds regularly shifting twice every day, and blowing from the sea towards the land during the day time, and from the land towards the sea in the night. These breezes do not blow with an equal degree of force throughout the whole day and night, but are perpetually varying, being always strongest about mid-day and midnight, and becoming gradually weaker till the time of change in the evening and morning; about which time the air continues for a short space perfectly calm: but in a little the breeze begins to be felt on the side opposite to that from which it blew last, so faint at first as hardly to be perceived; but by degrees acquiring greater strength, it goes on increasing for five or six hours, after which it again as gradually sinks and dies away. They always blow directly off or towards the shore, and never extend their influence to a great distance from it, although this is varied by particular circumstances in different places; as they never extend so far from the points of capes and promontories, as in deep bays; nor upon the windward, as lee-shores.

These breezes are produced by the same cause which gives rise to the trade-wind, *viz.* the heat of the sun. In these warm regions the days and nights are nearly of an equal length throughout the whole year; the sun rising high in the day time, and descending almost perpendicularly at night; which occasions a much greater

variation between the heat of the day and night than is experienced in the more temperate climates; and it is this great difference between the heat of the night and day which produces the breezes. For the rays of the sun are reverberated from the land during the day-time, much more powerfully than from the sea, whose surface is constantly evaporating; and the air above the land is rendered much warmer, and consequently more rarefied than above the sea; so that a current of air necessarily takes place at that time from the sea towards the land, increasing and diminishing in strength as the heat increases or declines. But when the sun descends below the horizon, the evaporation from the surface of the sea is stopped or greatly diminished, and the cold which it occasioned is of consequence removed: the reverberation of the sun's rays from the surface of the earth is likewise removed, and the air above the land quickly resumes its natural degree of cold, which is always greater than the sea when the influence of the sun is withdrawn: so that the air above the sea becomes warmer during the night than that above the land, and a current of air is of course established from the land to the sea, which forms the land-breeze, which acts as uniformly, although less powerfully, than the sea-breeze; blowing at first gently as the air begins to cool, and gradually gathering strength as the sun retires below the horizon; till his influence begins to be full again in the morning, when it gradually gives place to the more powerful influences of the sea-breeze. These breezes are not, however, entirely confined to the torrid zone. They are even felt in more northern regions; the sea-breeze in particular being almost as perceptible during the summer season along the coasts of the Mediterranean and the Levant, both on the African, European, and Asiatic shores, as within the tropics. Even in our own colder climate, the effects of this are often sensibly felt during the summer season; although, from the length of the day and shortness of the night, the difference between the heat of these is far less than in warmer climates. And although the shortness of our nights prevents us from feeling a nocturnal breeze, similar to the land-breezes of the torrid zone; yet in every serene evening, we have an opportunity of observing a phenomenon, proceeding from a similar cause with that which occasions them in warmer climates. For as the waters retain their heat longer than the earth after the sun withdraws, the moisture which was raised during the heat of the day to a small distance from the earth's surface is quickly condensed by the cold of the evening, and falls down in copious dews; whereas that which is above the surface of the water is more slowly condensed, by reason of the heat which that element retains longer, and hovers at a small distance above it in the form of a dense vapour, which slowly subsides as it loses its heat. This is the cause of those low mists which are so often seen hovering above the surface of rivers and other waters in the evenings towards the end of summer.

It was already observed, that in the Indian ocean the general trade-wind only took place in some parts to the south of the equator. To the north of the line, and in some places to the south of it in that ocean, the general trade-wind only blows regularly for six months; and during the other six months the wind blows in a direction entirely opposite. It is these winds, which

shift thus regularly, which are called *monsoons*, although they are also sometimes called *trade-winds*.

At the equator the days and nights are always of an equal length throughout the whole year; so that the heat being thus equally divided, it never arrives to such an intense degree as to be insupportable to the inhabitants. And as there is no vicissitude of seasons at the equator, so at the poles they never experience the more pleasing vicissitudes of day and night, the sun never setting during the summer season, nor rising above the horizon during the winter: and although the day decreases in length as we recede from the pole, from 6 months to 24 hours; yet in all high latitudes the sun descends for such a short space below the horizon, and in such an oblique direction, that the difference between the heat of the day and night is but very inconsiderable. From which it follows, that during this season, when the sun continues to act with such uninterrupted influence upon the surface of the earth, the air will then be rarefied more above the dry land than upon the surface of the water; so that a wind would naturally set in at that time from the sea towards the land, similar to the diurnal sea-breezes in the warmer climates; and on the contrary, during the winter season, the air in these northern regions being colder above the land than the water, the winds will naturally blow from the land towards the sea, similar to the land-breezes of the torrid zone. But as the influence of the sun, although of longer continuance, is in general more languid in climates of a high latitude than in those near the line, it is not to be expected that these effects will follow with the same regularity as in the torrid zone; being more apt to be interrupted by lesser causes which affect the atmosphere and produce winds in different directions. Yet these are not so totally interrupted but that we can easily trace their effects even in our own cold climate: for during the summer season, the large continent to the east of us, being more heated than the Atlantic ocean westward, produces a general tendency of the current of air towards the east, inasmuch that westerly winds are observed to prevail more than any other, not only here, but in all the frontier countries on the continent, during the summer season. And easterly winds become again more prevalent in the winter and spring. On the contrary, it is observed in North America, that the easterly winds prevail more in summer than at any other time; and the west winds always prevail during the cold months of winter. The same effects take place with a greater degree of constancy in other parts of Europe, particularly in Greece, and the countries in that neighbourhood; as the ancient Greeks have particularly remarked, that the winds blew from the south during the heat of summer, particularly about the dog-days, and from the north during the colder weather of winter.

Any attentive reader, who has accompanied us thus far, will readily see, that the monsoons which take place in the Indian ocean proceed from the same general cause. For when the sun, in his annual course, has crossed the line, and comes to act very strongly upon the extensive countries of Arabia, Persia, China, and the other parts of India, these become heated to a much higher degree than the ocean to the south of them; and the air above these extensive countries being so much rarefied, naturally draws the wind towards that place, which

Wind. which, by overcoming the general trade-wind, produces the southerly monsoons which take place in all those seas during the months of April, May, June, July, August, and September. But when the sun has again retreated towards the southern hemisphere, this great degree of heat in these countries subsides, and the genuine trade-wind again resumes its natural course; forming what they call the *northerly monsoon*, which blows in the months of October, November, December, January, February, and March: and as the continent of Asia now assumes a greater degree of cold than the Atlantic and Pacific oceans in the same latitude, it produces a brisker and more steady gale during the continuance of this monsoon, than is ever experienced in the general trade-wind.

Having thus explained the nature of the monsoons in general, we shall proceed to consider the particulars which influence the direction of these in those parts where they take place. In all that part of the Indian ocean which lies between the island of Madagascar and Cape Commarin, the wind blows constantly from the W. S. W. between the months of April and October; and in the opposite direction from the month of October till April, although with some variation in different places, as these winds are neither so strong nor constant in the bay of Bengal as in the Indian ocean. And it is likewise remarkable, that the S. W. winds in these seas are generally more southerly on the African side, and more westerly on the Indian, as appears distinctly in the map. But these variations are not repugnant to the general theory. For it is sufficiently known, that high lands in every part of the globe are much colder than low and flat countries; and as that part of Africa is very high and mountainous, the cold in these regions is much greater than in the more flat countries of Arabia and India; so that the wind naturally blows from these cold regions, in the summer season, towards the warmer continent of Asia; which occasions those inflexions of the wind to the eastward which take place in these seas during the summer months; and is still farther assisted by the peninsula of India, the kingdom of Siam, and the islands of Sumatra and Java, on the eastern part of this ocean, lying so much farther south than the kingdoms of Arabia and Persia; so that these, being more heated than the ocean to the westward, naturally draw the wind towards them, and produce the easterly variation of the monsoon which takes place in this part of the ocean, while the warm and sandy deserts of Arabia draw the winds more directly northward near the African coast.

In the eastern parts of the Indian ocean, beyond the island of Sumatra, through the gulph of Siam and bay of Tonquin, and along the southern parts of China, and among the Philippine islands, &c. to the north of the equator, the monsoons observe a different direction, blowing nearly due south and north. Here the greatest part of the warm continent is to the west of this district, which makes the wind naturally assume this direction. A little to the east of this, among the Marianné islands, the general trade-wind takes place, there being no continent to the north of them to occasion monsoons.

The monsoons are as regular in the eastern part of the Indian ocean to the south of the equator, as they

are to the north of it; as here a northern monsoon sets in from the month of October till April, and a southern from April to October. And here, as to the north of the line, we find the direction of the monsoons varying according to particular circumstances in different places: for about the island of Sumatra, and towards the west end of Java, the monsoons set in nearly from the north and south; but towards Celebes and Timur, they begin to tend a little more to the east and west, gradually declining as they approach the coast of New Guinea; near to which the northerly monsoon from October till April blows from the N. W. and the opposite monsoon from the S. E. between October and April. The reader will easily perceive that these monsoons are occasioned by the continent of New Holland and Guinea; which being heated by the sun when in the southern signs, draws the wind towards that in the summer season, in the same manner as the continent of Asia produces the monsoons to the north of the line. And it is likewise sufficiently plain, that the inflexion of these periodical winds about Celebes and Timur is occasioned by that part of the continent called *New Guinea* jutting out so near to the equator to the east of these, and drawing the wind toward that quarter.

These are the most general and extensive monsoons which take place in our globe. But there are other periodical winds, which occur in particular places in these warm regions, that deserves particular attention.

In the Red Sea, the monsoon shifts as regularly as in other places; but being influenced by the coasts, it tends a little more to the north and south than in the Indian ocean.

On the south coast of Africa, to the south of Cape Corientes, and about the southern parts of the island of Madagascar, the regular trade-wind from the S. E. takes place between October and April; but from April till October the wind blows from the W. or N. W. and is at that season exceedingly cold. This is evidently occasioned by a cause already taken notice of: for notwithstanding the high and cold nature of this continent, yet when the sun is to the south of the line, his powerful influence at that season so far abates their natural degree of cold, as not to interrupt the general trade-wind between the months of October and April: But when he returns to the northern hemisphere, the high mountains of Africa resume their native coldness, and repel the general trade-winds by their cold and more powerful blast, so as to produce the intemperate monsoon which here takes place between the months of April and October.

From Mozambique to Cape Guardafuy, at the mouth of the Red Sea, the monsoons are a little more irregular than in the other parts of the Indian ocean. For it is observed, that between October and January the winds are variable, although chiefly from the north. In January the N. E. monsoon sets in, and continues regular till the month of May. From May till October the winds again become variable, but blow chiefly from the southern points; but in the months of June, July, and August, there are frequent calms, especially about the bay of Melinda, which sometimes continue for several weeks together, and extend only about 100 leagues from shore.

Wind.

Wind.

Before we can explain the cause of this irregularity clearly, it will be necessary to attend to the direction of the wind on each side of this track at each particular season. In the months of October, November, and December, the winds are here variable, but chiefly from the north. Now during these three months, the wind to the south of this beyond Cape Corientes blows from the S. E. at the Red Sea, and all to the north of this the wind during this season of the year is from the N. E. And as the sun is then perpendicular to the bay of Melinda, these opposite winds here meeting and opposing one another, and being both of them stopped in their course westward by the cold regions of Africa near the Mountains of the Moon, will naturally produce the variable winds here observed, according as the one or the other of these three balancing powers shall predominate: although, as the coast here runs away towards the south-west, it is natural to expect that the northerly wind, which follows the same direction, should more frequently prevail than those which are opposed by it; especially when we consider, that the island of Madagascar, now beginning to be warmed by the influence of the sun, will concur in drawing the wind to the southward; and when the continent of Africa is more heated in the months of January and February, it does not oppose the easterly monsoon, so that the winds become then more fixed than before. But in the months of June, July, and August, the wind to the south of Cape Corientes is from the N. W.; and near the Red Sea, and throughout the northern part of the Indian ocean, the S. W. monsoon is then in its greatest vigour; so that on each end of this district the wind is blowing in an opposite direction; from which results these calms about Melinda, which we just now mentioned.

This much may suffice for the shifting winds on the African and Asiatic coasts. As to America, the only places where the wind shifts regularly are, the bays of Honduras and Campeachy on the east, and that of Panama and some parts on the coast of Mexico on the west, with a small track upon the coast of Brazil. In the south part of the bay of Honduras, between Cape Gracia de Dios and Cape la Bela, the common trade-wind between E. and N. E. blows between March and November; from October till March there are westerly winds, not constant or violent, but blowing moderately sometimes two or three days, or a week; and then the easterly breeze may again prevail for an equal length of time. The reason of the peculiarity here observed is this: During the summer season, the high land on the isthmus of Darien is so much warmed as not to interrupt the course of the general trade-winds; but when he retires to the southern hemisphere, the cold upon the isthmus at that season becomes so great, as to condense the air to such a degree as to repel the trade-wind for some time: but not being cooled to such an intense degree as in some of the larger continents, the trade-wind at times overcomes and repels these land-breezes in its turn, and produces the phenomena above described. And that this is really the case, appears evident from this circumstance, that the land breezes are most prevalent and of longest duration in the coldest months of December and January; before and after which two months, the trade-wind being generally checked only a day or two about the

full or change of the moon. As these western breezes on this coast take their rise from the same cause as the diurnal land-breeze in warm climates, they may be considered as land-breezes of two or three days continuance, and forming an intermediate step between the land-breezes and monsoons. Although the influence of these breezes is felt farther off at sea than the common diurnal breeze, yet they do not extend a great way, being seldom felt above 20, 30, or 40 leagues from shore; and about Cape La Vela, which is much exposed to the east wind, these breezes seldom extend above eight or ten leagues from shore. Land-breezes of the same nature, and proceeding from similar causes, are also experienced in the winter season in the bay of Campeachy, which are there known by the name of *Smafenta winds*. Beyond Cape la Vela these western breezes are not felt, which is undoubtedly occasioned by the whole of that coast as far as Cape St Augustine being so much exposed to the general trade-wind, which here sweeps along the coast with so much violence, as almost totally to repress the weaker influence of the breezes. But between Cape St Augustine and St Catharine's island, or a little farther, we again meet with a variation of the wind at different seasons, as it is here observed to blow in an E. or N. E. direction from September till April, and from April till September from the S. W. This variable wind, or monsoon, like the others on this coast, extends but for a very short way from shore, and is evidently occasioned by the same causes as the other periodical winds. For in the summer months (which in this climate is between September and April), the land of the continent being heated by the sun, draws the trade-wind from its common course of S. E. a little to the westward; and as the coast here tends towards the S. W. the wind in some measure (as it always does) follows the same direction, and produces this E. N. E. monsoon. But in the winter, when this region becomes more cool, the east wind is repelled by the dense cold air from the mountains; by which means it is bent to the northward, and is forced along the coast to Cape St Augustine; where, meeting with no further hindrance, it again falls in with the general trade-wind, and is carried along with it in its proper direction.

We have purposely omitted mentioning the winds on the west coasts of Africa and America till the others were explained, as the causes of the peculiarities here observed will be now more easily comprehended. On the coasts of Chili and Peru, in America, from 25° or 30° of south latitude to the line; and on the parallel coast of Angola, &c. in Africa, the wind blows all the year from the south, varying in its direction a little in different places according to the direction of the coast, towards which it always inclines a little. But whatever is the direction at any one place, it continues the same throughout the whole year without any variation, and always blows from some southerly point. But there is this difference between this wind upon the coasts of Chili and Angola, that it extends much farther out to sea upon the former than upon the latter.

In order to explain the cause of this singular phenomenon, it is necessary to recollect, that the general trade-wind is produced by the concurrence of two separate causes. One is the great heat of the equatorial region,

Wind.

Wind. region, by which alone would be produced a constant north or south wind. The other is the diurnal revolution of the earth, which would cause a perpetual tendency of the air in these warm regions from east to west. From the concurrence of these two causes result the general trade-wind, which would constantly blow from the S. E. or N. E. as we have already demonstrated. But if any one of these two causes, in any particular place, is prevented from producing its full effect, while the other continues to exert its influence, the general direction of the wind will be varied, and it will assume another. Thus, if the east wind was prevented from acting in any particular place, while nothing interrupted the south or north wind, it is evident that the air would rush towards the equator in that direction which was nearest and easiest, whether that should be pointing eastward or westward. Now as the high mountains in the internal parts of Africa and America interrupt the course of the east wind near the surface of the earth, while these coasts of which we now treat are entirely open to the south, the wind naturally rushes along the coasts of Chili and Angola from north to south; and as the low lands near the shore, in these warm regions, is generally warmer than the sea, the wind will naturally point in towards the shore, as is generally observed to happen.

This, then, is the obvious cause of the south wind which always prevails upon the coasts of Chili and Peru, as well as along the shores of Angola, Loango, &c. But it is only near the shore that this can take place; nor can it extend to a great height above these low and fertile regions. For as the internal parts of these countries are exceedingly high, but more especially the Andes of America, which experience a perpetual degree of cold more intense than some polar regions ever experience; the air must here be condensed to a very great degree, and send forth from these high regions a perpetual wind to every side, which occasions almost all the peculiarities that have been remarked in these climates: for by opposing the general current of the trade-wind upon the eastern part of these continents, they produce these deluges of rain which supply the immense rivers of the Amazons, La Plata, &c. these do not, like the Nile and Gambia, swell only at a particular season, and then shrink into a diminutive size again; but continue throughout the whole year, with less variation of size, to pour their immense floods of water into the ocean. These cold winds likewise stretching to the westward, at a considerable distance above the warmer regions of the sea-coast, at length descend as low as the ocean, and form the general trade-wind, and occasion that unusual degree of cold which mariners have so often complained of even under the line to the westward of America. To the same cause also must we attribute the thick fogs so common upon the southern parts of Chili and along the coasts of Peru, with the other peculiarities of that singular climate about Lima and the kingdom of Valles in South America; for the vapours which are exhaled in such great abundance in the warm regions on the sea-shore, are, at a little height above the earth, condensed by the cold winds which come from the mountains, and form these thick mists which are so often observed in this climate. The same effects are felt in some degree on the similar coast of Africa. But

as the mountains of Africa are not so high as the Andes of America, nor approach so near the western coast, the effects are less sensible here than in America. The great height of the Andes above the mountains of the similarly situated country of Africa, is the only reason why the effects on that coast are not felt to an equal degree, although similar in kind.

A more singular deviation from the general trade-wind is observed to take place on the African and American coasts to the north of the line, than those we have taken notice of to the south of it. For it is observed, that from California to the bay of Panama, all along the coasts of New Spain, the winds blow almost constantly from the west or S. W. nearly directly opposite to the trade-wind; and on the coast of Africa from Cape Bayador to Cape Verde, they blow chiefly from the N. W. standing in upon the shore; from thence the wind bends gradually more and more from the north to the west, and so round to the S. W. all along the coast of Guinea, as will be distinctly seen by the map. After what we have said of the winds on the southern parts of these regions, it will be unnecessary to spend much time in explaining the cause of these peculiarities, as it will evidently appear that they are nearly the same, the variations here observed being occasioned by the particular direction of the coast.— Thus, along the coast of New Spain, the wind blows nearly the same direction in every place, as there are no remarkable bendings on the coast; being uniformly drawn towards the shore by the great heat of the low part of the continent near the sea; which in these regions is always more heated than the water of the ocean, and occasions that inflection. But as the coast of Africa is more irregular, the winds also are found to be more different in their direction. To the north of Cape Verde, as the coast stretches nearly south and north, the wind, being drawn towards it a little, blows from the N. W. But beyond that, the coast bends more eastward to Cape Palmas; from which it runs E. or N. E. all along the coast of Guinea, the wind shifting gradually more and more to the west, still pointing in upon the coast. And as there is nothing to oppose the current of air, which comes from the south along the coast of Angola, it stretches forward till it comes within the influence of the coast of Guinea, and is there drawn in towards the shore in a S. W. direction. But as it is only the lower regions of the coast of Guinea which are so much warmed, the high mountains within continuing cold; the northerly wind coming from these meeting and opposing the southerly winds in the higher regions of the air, by their mutual conflicts occasion those incessant rains and tremendous thunder so remarkable along the whole of this uncomfortable coast.

It has been often observed by mariners, that there is a track of sea to the west of Guinea from five to ten degrees of north latitude, in which the trade-wind blows with less steadiness than in any other part of that ocean, being almost constantly troubled with calms and tornadoes; the cause of which the reader will perceive by inspecting the map, as he will easily see that the winds are drawn from this quarter almost in every direction: so that there can be here no constant wind; but being exhausted of its air, it must become lighter than the circumjacent parts, and must then be

Wind.

supplied from either side, as chance or occasional circumstances may direct, which occasions those sudden furies and tornadoes here observed.
